# Italian Greenhouse Gas Inventory 1990-2003

## National Inventory Report 2005

## Italian Greenhouse Gas Inventory 1990-2003

## National Inventory Report 2005

Daniela Romano, Rocio Condor, Mario Contaldi, Riccardo De Lauretis, Eleonora Di Cristofaro, Domenico Gaudioso, Barbara Gonella, Marina Vitullo

APAT - Agency for the Protection of the Environment and for Technical Services

Annual Report for submission under the UN Framework Convention on Climate Change and the European Union's Greenhouse Gas Monitoring Mechanism

### Authors

Rocio Condor (agriculture), Mario Contaldi (energy), Riccardo De Lauretis (energy, industrial processes), Eleonora Di Cristofaro (solvent and other product use) Domenico Gaudioso (industrial processes, waste) Barbara Gonella (industrial processes, waste), Daniela Romano (general coordination and editing, cross cutting issues), Marina Vitullo (land use, land use change and forestry)

Execu	JTIVE SUMMARY	12
ES.1	BACKGROUND INFORMATION ON GREENHOUSE GAS INVENTORIES AND	
	CLIMATE CHANGE	12
ES.2	SUMMARY OF NATIONAL EMISSION AND REMOVAL RELATED TRENDS	12
ES.3	OVERVIEW OF SOURCE AND SINK CATEGORY EMISSION ESTIMATES AND TRENDS	14
ES.4	OTHER INFORMATION	15
SOMM	ARIO (ITALIAN)	16
1.	INTRODUCTION	17
1.1	BACKGROUND INFORMATION ON GREENHOUSE GAS INVENTORIES AND	
	CLIMATE CHANGE	17
1.2	DESCRIPTION OF THE INSTITUTIONAL ARRANGEMENT FOR	
	INVENTORY PREPARATION	18
1.3	BRIEF DESCRIPTION OF THE PROCESS OF INVENTORY PREPARATION	18
1.4	BRIEF GENERAL DESCRIPTION OF METHODOLOGIES AND DATA SOURCES USED	19
1.5	BRIEF DESCRIPTION OF KEY SOURCE CATEGORIES	22
1.6	INFORMATION ON THE $QA/QC$ PLAN INCLUDING VERIFICATION AND	
	TREATMENT OF CONFIDENTIALITY ISSUES WHERE RELEVANT	23
1.7	GENERAL UNCERTAINTY EVALUATION, INCLUDING DATA ON THE OVERALL	-
	UNCERTAINTY FOR THE INVENTORY TOTALS	25
1.8	GENERAL ASSESSMENT OF THE COMPLETENESS	26
2.	TRENDS IN GREENHOUSE GAS EMISSIONS	28
2.1	DESCRIPTION AND INTERPRETATION OF EMISSION TRENDS FOR AGGREGATE	20
2.1	GREENHOUSE GAS EMISSIONS	28
2.2	DESCRIPTION AND INTERPRETATION OF EMISSION TRENDS BY GAS	20 29
	2.1 Carbon dioxide emissions	2)
	2.2 Methane emissions	
	2.3 Nitrous oxide emissions	
2.2	P.4 Fluorinated gas emissions DESCRIPTION AND INTERPRETATION OF EMISSION TRENDS BY SOURCE	33
		33
	2.1 Energy	
	2.2 Industrial processes	
	3.3 Solvent and other product use	
	2.4 Agriculture	
2.3		
2.4	DESCRIPTION AND INTERPRETATION OF EMISSION TRENDS FOR	
•	INDIRECT GASES AND SO <sub>2</sub>	37
3.	ENERGY [CRF SECTOR 1]	39
3.1	INTRODUCTION	39
3.2	KEY SOURCES	39

### **Executive Summary**

### ES.1. Background information on greenhouse gas inventories and climate change

The United Nations Framework Convention on Climate Change (FCCC) was ratified by Italy in the year 1994 through law no.65 of 15/01/1994. As a Party to the Convention, Italy is committed to develop, publish and regularly update national emission inventories of greenhouse gases (GHGs) as well as to formulate, implement, publish and regularly update programmes addressing anthropogenic GHG emissions.

The Kyoto Protocol, adopted in December 1997, has established emission reduction objectives for Annex B Parties (i.e. industrialised countries and countries with economy in transition): in particular, the European Union as a whole is committed to a 8% reduction within the period 2008-2012, in comparison with 1990 levels. For Italy, the EU burden sharing has established a reduction objective of 6.5% in the commitment period, in comparison with 1990 levels.

Subsequently, on 1<sup>st</sup> June 2002, Italy ratified the Kyoto Protocol with the law no.120 of 01/06/2002. The ratification law prescribed also the preparation of a National Action Plan to reduce greenhouse gas emissions, which was adopted by the Interministerial Committee for Economic Planning (CIPE) on 19<sup>th</sup> December 2002.

The Kyoto Protocol finally entered into force in February 2005.

In order to establish compliance with national and international commitments, the national GHG emission inventory is compiled and communicated annually to the competent institutions through compilation of the Common Reporting Format (CRF), according to the guidelines provided by the United Nations Framework Convention on Climate Change and the European Union's Greenhouse Gas Monitoring Mechanism. An annual inventory submission shall consist of a national inventory report (NIR) and the common reporting format (CRF) tables as specified in the Guidelines on reporting and review of greenhouse gas inventories from Parties included in Annex 1 to the Convention, implementing decisions 3/CP.5 and 6/CP.5, doc.FCCC/SBSTA/2002/L.5/Add.1. Detailed information on emission figures as well as estimation procedures, including all the basic data needed to carry out the final estimates, are requested in order to improve the transparency, consistency, comparability, accuracy and completeness of the inventory provided.

The national inventory is updated annually in order to reflect revisions and improvements in the methodology and availability of new information. Adjustments are applied retrospectively to earlier years, which accounts for any difference in previously published data.

This report is compiled according to the guidelines on reporting as specified in the document FCCC/SBSTA/2002/L.5. It provides an analysis of the Italian GHG emission inventory communicated to the Secretariat of the Climate Change Convention and to the European Commission in the framework of the Greenhouse Gas Monitoring Mechanism for the year 2003, including the entire time series 1990-2003.

Emission estimates comprise the six direct greenhouse gases under the Kyoto Protocol (carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, sulphur hexafluoride) which contribute directly to climate change owing to their positive radiative forcing effect and four indirect greenhouse gases (nitrogen oxides, carbon monoxide, non-methane volatile organic compounds, sulphur dioxide).

The CRF files and other related documents can be found at the website www.sinanet.apat.it/aree/atmosfera/emissioni/emissioni.asp.

### ES.2. Summary of national emission and removal related trends

Total greenhouse gas emissions, in  $CO_2$  equivalent, excluding emissions and removals of  $CO_2$  from land use change, increased by 11.6% between the base year and 2003 (from 510 to 570 million  $CO_2$  equivalent tons), while the national Kyoto target is a reduction of 6.5% as compared the base year levels by the period 2008-2012.

The most important greenhouse gas,  $CO_2$ , which accounted for 85.5% of total emissions in  $CO_2$  equivalent in 2003, showed an increase of 13.2% between 1990 and 2003. In the energy sector, in particular, emissions in 2003 were 14.2% greater than in 1990.

 $CH_4$  and  $N_2O$  emissions were equal to 6.1% and 7.4%, respectively, of the total  $CO_2$  equivalent greenhouse gas emissions in 2003.  $CH_4$  emissions decreased by 9.6% from 1990 to 2003, while  $N_2O$  increased by 6.1%.

Other greenhouse gases, HFCs, PFCs and SF<sub>6</sub>, ranged from 0.3% to 1% of total emissions; at present, variations in these gases are not relevant to reaching the objectives for emissions reduction. Table ES.1 illustrates the national trend of greenhouse gases for 1990-2003, expressed in  $CO_2$  equivalent terms, by substance and category.

Table ES.2. Summary of emission trend by source category and gas in CO<sub>2</sub> equivalent (Gg)

The energy sector is the largest contributor to national total GHG emissions with a share, in 2003, of 84% out of the total GHG emissions. Emissions from the energy sector increased by about 13.8% from 1990 to 2003. Substances with the highest increase rates are CO<sub>2</sub>, whose levels increased by 14% from 1990 to 2003 and accounts for 96.4% of the total in the energy sector, and N<sub>2</sub>O which shows an increase of 22% but its share out of the total is only 2.2%; CH<sub>4</sub>, on the other hand, shows a decrease of 18% from 1990 to 2003 but it is not relevant on total emissions, accounting only for 1.4%. Specifically, in terms of total CO<sub>2</sub> equivalent, the most significant increase is observed in the

transport and energy industries sectors, about 25% and 19% from 1990 to 2003, respectively; these sectors, altogether, account for 62% of total energy emissions.

For the industrial processes sector, emissions show a total increase of 13% from the base year to 2003. Specifically, by substance,  $CH_4$  decreased by 46%, but it accounts only for 0.1%, while N<sub>2</sub>O, whose levels share 18% of total industrial emissions, raised up to 28%. A considerable increase is observed in F-gas emissions (about 245%) and the level of these gases on total emissions is 14%.

In contrast, emissions from the solvent and other use sector, which refer to  $CO_2$  and  $N_2O$  emissions except for gases other than greenhouse, decreased by 12% from 1990 to 2003. The reduction is mainly to be attributed to a decrease by 24% in  $CO_2$  emissions, which account for 59% of the sector. The most relevant reduction affected both the paint application sector (-18%), which accounts for 48%, and other use of solvents in related activities (-24%), such as domestic solvent use other than painting, printing industries, vehicle dewaxing, which account for 38%. Emissions from metal decreasing and dry cleaning activities, also decreased (-57%) but account for only 5%. The level of  $N_2O$  emissions, on the other hand, increased by 15% from 1990 to 2003.

For agriculture, emissions refer to  $CH_4$  and  $N_2O$  levels, which account, in 2003, for 42% and 58% of the sector, respectively. The decrease observed in the total emissions (-5%) is mostly due to the decrease of  $CH_4$  emissions from enteric fermentation (-11%), which account for 28%, and to a minor decrease in emissions from agricultural soils (-2%), which account for most of the sectoral emissions.

Finally, emissions from the waste sector decreased by 5.5% from 1990 to 2003 due to the reduction in the waste incineration sector (-27%), which account for 4% of waste emissions, as well as those from solid waste disposal (-6%) which account for 76%.

The most important greenhouse gas in this sector is  $CH_4$  which accounts for 90% of the sectoral emissions and shows a decrease of 4% from 1990 to 2003. N<sub>2</sub>O levels increased by 4% whereas  $CO_2$  decreased by 66%; these gases account for 9% and 1%, respectively.

## **ES.4.** Other information

In Table ES.3 emission trends of NO<sub>X</sub>, CO, NMVOC and SO<sub>2</sub> from 1990 to 2003 are summarised.

Indirect greenhouse gases and SO <sub>2</sub>	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
Emissions in ktons														
NO <sub>X</sub>	1,947	2,000	2,019	1,921	1,840	1,808	1,732	1,654	1,553	1,456	1,378	1,367	1,276	1,260

 Table ES.3. Total emissions of indirect greenhouse gases and SO<sub>2</sub> (1990-2003)

All gases show a significant reduction in 2003 as compared to 1990 levels. The highest reduction is observed for  $SO_2$  (-72%), while CO emissions reduced by 38% and NO<sub>X</sub> and NMVOC levels showed a decrease by about 35%.

### Sommario (*Italian*)

Nel documento "Italian Greenhouse Gas Inventory 1990-2003. National Inventory Report 2005" si descrive la comunicazione annuale italiana dell'inventario delle emissioni dei gas serra in accordo a quanto previsto nell'ambito della Convenzione Quadro sui Cambiamenti Climatici delle Nazioni Unite (UNFCC) e del Meccanismo di Monitoraggio dei Gas Serra dell'Unione Europea.

Ogni Paese che partecipa alla Convenzione, infatti, oltre a fornire annualmente l'inventario nazionale delle emissioni dei gas serra secondo i formati richiesti, deve documentare in un *report*, il *National Inventory Report*, la serie storica delle emissioni. La documentazione prevede una spiegazione degli andamenti osservati, una descrizione dell'analisi delle sorgenti chiave, *key sources*, e dell'incertezza ad esse associata, le referenze delle metodologie di stima e le fonti dei dati di base e dei fattori di emissione utilizzati per le stime, una descrizione del sistema di *Quality Assurance/Quality Control* a cui è soggetto l'inventario e le attività di verifica effettuate sui dati.

Il *National Inventory Report* facilita, inoltre, i processi internazionali di revisione a cui le stime di emissione dei gas serra sono sottoposte al fine di verificarne la rispondenza alle proprietà di trasparenza, consistenza, comparabilità, completezza e accuratezza nella realizzazione dell'inventario, richieste esplicitamente dalle Convenzioni suddette. Nel caso in cui durante il processo di review vengano identificati eventuali errori nel formato di trasmissione o stime non supportate da adeguata documentazione e giustificazione nella metodologia scelta, il Paese viene invitato ad una revisione delle stime di emissione.

I dati di emissione dei gas-serra, così come i risultati dei processi di *review*, sono pubblicati sul sito web del Segretariato della Convenzione sui Cambiamenti Climatici www.unfccc.int.

I dati di emissione della serie storica italiana sono disponibili sul sito web www.sinanet.apat.it/aree/atmosfera/emissioni/emissioni.asp.

Da una analisi di sintesi della serie storica dei dati di emissione dal 1990 al 2003, si evidenzia che le emissioni nazionali totali dei sei gas serra, espresse in  $CO_2$  equivalente, sono aumentate del 12% nel 2003 rispetto all'anno base (corrispondente al 1990 per  $CO_2$ ,  $CH_4$  e  $N_2O$  ed al 1995 per HFC, PFC e SF<sub>6</sub>), a fronte di un impegno nazionale di riduzione del 6.5% entro il periodo 2008-2012.

In particolare, le emissioni complessive di  $CO_2$  sono pari all'85% del totale e risultano nel 2003 superiori del 13% rispetto al 1990, mentre le emissioni relative al solo settore energetico sono aumentate del 14.2%. Le emissioni di metano e di protossido di azoto sono pari rispettivamente a circa il 6% e l'7% del totale e presentano andamenti in diminuzione per il metano (-9.6%) e in crescita (+6.1%) per il protossido di azoto. Gli altri gas-serra, HFC, PFC e SF<sub>6</sub>, hanno un peso complessivo intorno all'1% sul totale delle emissioni; le emissioni di questi ultimi gas sono in forte crescita per quanto riguarda gli HFCs ed in diminuzione per gli altri due. Anche se al momento non rilevanti ai fini del raggiungimento degli obiettivi di riduzione delle emissioni, il forte *trend* di crescita li renderà sempre più importanti nei prossimi anni.

## **Chapter 1 INTRODUCTION**

### 1.1 Background information on greenhouse gas inventories and climate change

In 1988 the World Meteorological Organisation (WMO) and the United Nations Environment Program (UNEP) established a scientific Intergovernmental Panel on Climate Change (IPCC) in order to evaluate the available scientific information on climate variations, examine the social and economical influence on climate change and formulate suitable strategies for the prevention and the control of climate change.

The first IPCC report in 1990, although considering the high uncertainties in the evaluation of climate change, emphasised the risk of a global warming due to an unbalance in the climate system originated by the increase of anthropogenic emissions of greenhouse gases (GHGs) caused by industrial development and use of fossil fuels. Hence the need of reducing those emissions, particularly for the most industrialised countries.

The first initiative was taken by the European Union (EU) at the end of 1990, when the EU adopted the goal of a stabilisation of carbon dioxide emissions by the year 2000 at the level of 1990 and requested Member States to plan and implement initiatives for environmental protection and energy efficiency. The contents of EU statement were the base for the negotiation of the United Nations Framework Convention on Climate Change (UNFCC) which was approved in New York on 9<sup>th</sup> May 1992 and signed during the summit of the Earth in Rio the Janeiro in June 1992. Parties to the Convention are committed to develop, publish and regularly update national emission inventories of greenhouse gases (GHGs) as well as to formulate, implement, publish and regularly update programmes addressing anthropogenic GHG emissions. Specifically, Italy ratified the convention through law no.65 of 15/1/1994.

The Kyoto Protocol, adopted in December 1997, has established emission reduction objectives for Annex B Parties (i.e. industrialised countries and countries with economy in transition): in particular, the European Union as a whole is committed to a 8% reduction within the period 2008-2012, in comparison with 1990 levels. For Italy, the EU burden sharing has established a reduction objective of 6.5% in the commitment period, in comparison with 1990 levels.

Italy ratified the Kyoto Protocol on 1<sup>st</sup> June 2002 through law no.120 of 01/06/2002. The ratification law prescribes also the preparation of a National Action Plan to reduce greenhouse gas emission, which was adopted by the Interministerial Committee for Economic Planning (CIPE) on 19<sup>th</sup> December 2002.

The Kyoto Protocol finally entered into force in February 2005.

In order to establish compliance with national and international commitments air emission inventories are compiled and communicated annually to the competent institutions.

Specifically, the national GHG emission inventory is communicated through compilation of the Common Reporting Format (CRF), according to the guidelines provided by the United Nations Framework Convention on Climate Change and the European Union's Greenhouse Gas Monitoring Mechanism (IPCC, 1997; IPCC, 2000; IPCC, 2003; EMEP/CORINAIR, 2001).

Detailed information on emission figures as well as estimation procedures, including all the basic data needed to carry out the final estimates, are requested in order to improve the transparency, consistency, comparability, accuracy and completeness of the inventory provided.

The national inventory is updated annually in order to reflect revisions and improvements in the methodology and the availability of new information. Adjustments are applied retrospectively to earlier years, which accounts for any difference in previously published data.

This report is compiled according to the guidelines on reporting as specified in the document FCCC/SBSTA/2002/L.5. It provides an analysis of the Italian GHG emission inventory communicated to the Secretariat of the Climate Change Convention and to the European Commission in the framework of the Greenhouse Gas Monitoring Mechanism for the year 2003, including the entire time series 1990-2003.

Emission estimates comprise the six direct greenhouse gases under the Kyoto Protocol (carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, sulphur hexafluoride) which contribute directly to climate change owing to their positive radiative forcing effect and four indirect greenhouse gases (nitrogen oxides, carbon monoxide, non-methane volatile organic compounds, sulphur dioxide).

The CRF files and other related documents can be found on the website www.sinanet.apat.it/aree/atmosfera/emissioni.

### **1.2 Description of the institutional arrangement for inventory preparation**

Italy is undertaking the actions to develop a national emission inventory system, National System, which involves and attributes specific roles and responsibilities to the different institutions which should collect and communicate basic data necessarily and timely for the GHG inventory compilation. As required by article 5.1 of the Kyoto Protocol, Annex I Parties shall have in place a National System by the end of 2006 at the latest for estimating anthropogenic greenhouse gas emissions by sources and removals by sinks and for reporting and archiving inventory information according to the guidelines specified in the UNFCC Decision 20/COP.7. In addition, the Decision of the European Parliament and of the Council concerning a mechanism for monitoring Community greenhouse gas emissions (280/2004/EC) requires that Member States establish a national greenhouse gas inventory system by the end of 2005 at the latest and that the Commission adopts the EC's inventory system by 30 June 2006.

Up to now, the Agency for the Protection of the Environment and for Technical Services (APAT) is recognized by the competent Ministries and Administrations, as responsible for the compilation of the National Air Emission Inventory through the collection, elaboration and diffusion of data. In particular, as National Reference Centre of the European Environment Agency (EEA), APAT is required to prepare the national atmospheric emission inventory in order to ensure compliance with international commitments concerning the protection of the environment (Framework Convention on Climate Change, Convention on Long Range Transboundary Air Pollution, European Directives on emission ceilings).

The Italian greenhouse gas inventory is compiled and updated annually by the Agency and officially communicated to the Secretariat of the Framework Convention on Climate Change and to the European Commission in the framework of the Greenhouse Gas Monitoring Mechanism, after endorsement by the Ministry for the Environment and Territory.

Although there is not an official National System in place, different institutions responsible for statistical data flow and publication are part of a National Statistical System (SISTAN) and therefore are asked periodically to update statistics; in spite of that, problems regarding timeliness and lack of transparency still occur. In the next months, APAT, on behalf of the Ministry for the Environment and Territory, will draft a plan for the establishment of a robust national system (building on the base of SISTAN), with a sound legal basis at a later stage.

### 1.3 Brief description of the process of inventory preparation

Data collection and timely availability are the main difficulties faced by Italy, up to now, which do not allow the submission of the emission inventory within the time scheduled. In fact, several sectoral statistics are available with significant delay: for instance, energy statistics and fuel consumption are published at the end of the year, or even later, and some industrial production statistics as well as agriculture and forestry statistics are published even two years later. Moreover, data are not always available with the necessary details and the use of proxy variables and indicators, even if overcoming these difficulties, would introduce further uncertainties in the estimates. At this aim, ad hoc expert panel, i.e transport, land use change and forestry, have been instituted on a voluntary basis in order to improve the completeness and transparency of the

inventory. Generally, the basic data needed for the preparation of the GHG inventory are energy statistics published by the Ministry of Production Activities (MAP) in the National Energy Balance (BEN), statistics on industrial and agricultural production published by the National Statistics Institute (ISTAT), statistics on transportation provided by the Ministry of Transportation, and data supplied directly by the relevant professional associations.

Emission factors and methodologies used in the estimation process are consistent with the IPCC Good Practice Guidance and supported by national experiences and circumstances. Final decisions are up to inventory experts, taking into account all the information available.

As far as industrial sources are concerned, emission data collected through the National Pollutant Emission Register (EPER) are taken into account as a verification of emission inventory estimates. According to the Italian Decree of 23 November 2001, data from the Italian EPER are validated and communicated by APAT to the Ministry of the Environment and the Territory and to the European Community within October of the current year for the previous year. These data are not used directly for the compilation of the inventory because industries communicate emission values only if they exceed specific thresholds; furthermore, basic data such as fuel consumption are not communicated and in some cases production are not split by product but considered as an overall figure. Anyway, EPER is a good basis for data checks and a way to facilitate contacts with industries which, in many cases, supply under request additional information as necessary for carrying out some sectoral emissions.

In addition, estimates are checked and verified also taking into account figures reported by industries in their annual environmental reports.

For large industrial point sources, emissions are registered individually, when communicated, based upon detailed information such as fuel consumption. Other small plants communicate their emissions which are also considered individually.

Emission estimates are drawn up for each sector. Final data are communicated to the UNFCC Secretariat filling in the CRF files. The process takes over annually; in the year t final emissions are calculated for the year t-2: in case of methodological changes or additional information, emissions are recalculated from the year 1990 onwards.

All the material, estimates and calculation sheets, as well as the documentation on scientific papers and the basic data needed for the inventory compilation, are stored and archived at the Agency.

## 1.4 Brief general description of methodologies and data sources used

A detailed description of methodologies and data sources used in the preparation of the emission inventory for each sector is outlined in the specific chapters. In Table 1.1 a summary of the activity data and the sources used in the inventory compilation is reported.

Methodologies are consistent with the Revised 1996 IPCC Guidelines, IPCC Good Practice Guidance and EMEP-CORINAIR Emission Inventory Guidebook (IPCC, 1997; IPCC, 2000; IPCC, 2003; EMEP/CORINAIR 2001); national emission factors are used as well as default emission factors from international guidebooks (IPCC, CORINAIR, EPA), in case national data are not available. The development of national methodologies is supported by background documents, even though not always available in English.

SECTOR	ACTIVITY DATA	SOURCE
1 Energy		
1A1 Energy Industries	Fuel use	Energy Balance - Ministry of Production Activities
		Major national electricity producers
1A2 Manufacturing Industries and Construction	Fuel use	Energy Balance - Ministry of Production Activities

		National Waste Observatory

Table 1.1 Activity data and sources for the Italian National Emission Inventory

Specific sector analyses are committed to ad hoc research teams or consultants when in depth investigation is needed and a high uncertainty in the estimates is present.

In Table 1.2 a summary of the methods and emission factors used in the compilation of the Italian inventory is reported. A more detailed table as communicated to the European Community in the framework of the monitoring mechanism of GHG emission inventory for the purpose of Article 4(1)(b) under the Implementing Provisions (EC, 2005) is included in Annex 8.

use different notations in one and the same cells with further explanation in the documentation box of the relevant Sectoral background data table Table 1.2 Methods and emission factors used in the inventory preparation

Activity data used in emission calculations and their sources are briefly described herebelow. In general, basic statistics for estimating emissions from the energy sector are fuel consumption published in the Energy Balance and provided by the Ministry of Production Activities. Additional

information for electricity production is provided by the major national electricity producers and for the industry sector by the major national industry corporation. On the other hand, for the transport sector, basic information for road transport, maritime and aviation, such as the number of vehicles, harbour statistics and aircraft landing and take-off cycles are provided in statistical yearbooks published both by the National Statistics Institute and the Ministry of Transportation. Other data are communicated by different associations.

For the other sectors, i.e. industrial processes, the annual production is provided by national and international statistical yearbooks; for solvents, the amount of solvent use is provided by environmental publications of sector industries and specific associations as well as international statistics. For agriculture, annual production data and number of animals are provided by the National Statistics Institute. For land use change and forestry, forest and soil surfaces are provided by the National Statistics Institute and the hectares burnt by State Forestry Corps. For waste, the main activity data are provided by the Agency for the Protection of the Environment and for Technical Services and the Waste Observatory.

In case basic data are not available proxy variables are considered in the estimation process; unpublished data are used only if supported by personal communication and confidentiality of data is respected.

All the material and documents used for the inventory emission estimates are stored at the Agency for the Protection of the Environment and for Technical Services.

After each reporting cycle, all database files, spreadsheets and electronic documents are archived so that the documentation and estimates could be traced back during the new year inventory compilation. Technical reports and emission figures are publicly accessible by website www.sinanet.apat.it/aree/atmosfera/emissioni.

### 1.5 Brief description of key source categories

A key source analysis has been carried out according to the Tier 1 and Tier 2 methods described in the IPCC Good Practice Guidance (IPCC, 2000). A key source category is defined as an emission source that has a significant influence on a country's GHG inventory in terms of the absolute level of emissions, the trend in emissions, or both. Key source categories are those which, when summed together in descending order of magnitude, add up to over 95% of the total emissions.

Key source categories	
CO <sub>2</sub> Stationary combustion liquid fuels	L, T
CO <sub>2</sub> Stationary combustion solid fuels	L, T
CO <sub>2</sub> Stationary combustion gaseous fuels	L, T
CO <sub>2</sub> Mobile combustion: Road Vehicles	L, T
CO <sub>2</sub> Cement production	L, T2
CH <sub>4</sub> Enteric Fermentation in Domestic Livestock	L, T
CH <sub>4</sub> from Solid waste Disposal Sites	L, T
Direct N <sub>2</sub> O Agricultural Soils	L, T
N <sub>2</sub> O Adipic Acid	L, T
Indirect N <sub>2</sub> O from Nitrogen used in agriculture	L, T
N <sub>2</sub> O Stationary combustion	L, T2
HFC, PFC substitutes for ODS	L, T
CO <sub>2</sub> Mobile combustion: Waterborne Navigation	L1, T2
CH <sub>4</sub> Fugitive emissions from Oil and Gas Operations	L, T
N <sub>2</sub> O Manure Management	L, T2
CH <sub>4</sub> Manure Management	L, T
N <sub>2</sub> O Mobile combustion: Road Vehicles	L, T
CO <sub>2</sub> Mobile combustion: Aircraft	T1
CO <sub>2</sub> Other industrial processes	T1
N <sub>2</sub> O Nitric Acid	T1
CO <sub>2</sub> Mobile combustion: Other	T1
CO <sub>2</sub> Fugitive emissions from Oil and Gas Operations	L2, T1
N <sub>2</sub> O from animal production	L2, T2
CH <sub>4</sub> Emissions from Wastewater Handling	L2, T2
CH <sub>4</sub> from Rice production	L2
CO <sub>2</sub> Emissions from solvent use	L2, T2
N <sub>2</sub> O Emissions from solvent use	T2
CH <sub>4</sub> Stationary combustion	L2
N <sub>2</sub> O Emissions from Wastewater Handling	T2

Table 1.3 Key source categories by the IPCC Tier 1 and Tier 2 approaches (L=Level, T=Trend)

National emissions have been disaggregated, as far as possible, into the categories proposed in the Good Practice Guidance; other categories have been added to reflect specific national circumstances. Both level and trend analysis has been applied. As far as both level and trend emission sources are concerned, 29 key sources were totally individuated. Results are reported in

Table 1.3. It should be noted that higher tiers are mostly used for calculating emissions from these sources as requested by the Good Practice Guidance (IPCC, 2000).

# 1.6 Information on the QA/QC plan including verification and treatment of confidentiality issues where relevant

A specific QA/QC system is being developed in the framework of the establishment of the National System, but QA/QC techniques and different verification procedures are already applied as part of the inventory estimation process.

The Italian Atmospheric Emission Inventory and the Italian Greenhouse Gas Inventory are compiled and maintained by the Agency for the Protection of the Environment and for Technical Services which is the Inventory Agency responsible for data submission. The whole inventory is compiled by the agency; scientific and technical institutions and consultants may help in improving information both on activity data and emission factors of some specific activities. All the measures to guarantee and improve the transparency, consistency, comparability, accuracy and completeness of the inventory are undertaken.

The quality of the inventory has improved over the years and further investigations are planned for all those sectors relevant in terms of contribution to total  $CO_2$  equivalent emissions and with a high uncertainty.

In addition to *routine* control activities related to completeness, consistency in the time series and correctness in the sum of sub-categories, specific quality control activities regard the accurate check of figures and documentation of those cases where methodological and data changes result in recalculations. Particular attention is also paid to the archiving and storing of all inventory data, supporting information, inventory records as well as all the reference documents.

Data entries are checked several times during the compilation of the inventory; special attention is paid to sources which show significant changes from a year to another or new sources. Final checks involve a consistency check on the whole time series. When revisions of estimation methodologies are applied, emissions are recalculated for the entire time series as a matter of course.

All the information used for the inventory compilation is traceable back to its source. The inventory is composed by spreadsheets to calculate emission estimates; activity data and emission factors as well as methodologies are referenced to their data sources, while all information and documentation are stored at the Agency so as to be consulted whenever needed. After each reporting cycle, all database files, spreadsheets and electronic documents are archived and documentation and estimates could be consulted during the new year inventory compilation.

Quality assurance procedures regard some verification activities of the inventory as a whole and at sectoral level. Drawbacks derive, in particular, from the communication of data to different institutions and/or at local level. The preparation of environmental reports where data are needed at different aggregation levels or refer to different contexts such as environmental and economic accountings is also a check for emission trends. At national level, for instance, emission time series are reported in the Environmental Data Yearbook published by the Agency; they are also published by the Ministry of Environment in the Report on the State of the Environment and communicated to the National Institute of Statistics to be published in their Environmental Statistics Yearbooks and used in the framework of the EUROSTAT NAMEA Project.

Comparisons of national activity data with data from international databases are usually carried out in order to find out the main differences and an explanation to them; this results in a better understanding and detail of the basic data. Such a comparison has mainly regarded data for the agriculture and industrial processes sectors. The results are reported in the specific chapters. Additional comparisons of emission estimates from industrial sectors with those published by the industry itself in the Environmental reports are carried out annually in order to assess the quality and the uncertainty of the estimates. In order to verify of the effectiveness of policies and measures undertaken by Italy to reduce greenhouse gas emissions to the levels established by the Kyoto Protocol, a study was carried out by Ecofys. In this framework an independent review and checks on emission levels were carried out as well as controls on the transparency and consistency of methodological approaches (Ecofys, 2001).

The quality of the inventory is also improved by the organization and participation in sector specific workshops. Furthermore, follow-up processes are set up in the framework of the WGI under the EC Monitoring Mechanism, which has up to now addressed to the improvement of methodologies in the waste sector as well methodologies to estimate emissions from international bunkers. Regarding this last point, national methodologies used to estimate emissions from aviation and marine bunkers were explained by the different countries at a specific European workshop on bunker fuels which involved the International Energy Agency and EUROCONTROL. The workshop aimed at comparing methodologies and discussed the most common problems among countries which is the split of fuel into domestic and international. For the waste sector, a workshop was held on methodologies to estimate emissions from different countries. The European Topic Center on Resource and Waste Management was also involved and documentation is available on the website at the ETC/ACC web site: <a href="http://air-climate.eionet.eu.int/meetings/past\_html">http://air-climate.eionet.eu.int/meetings/past\_html</a>.

International reviews also contribute to improve the inventory and identify areas where further improvements are needed. Specifically, the Italian GHG inventory was subjected to a centralised review by the UNFCC Secretariat; in response recalculation tables for all years have been provided and source not previously estimated have been included.

A specific procedure undertaken for improving the inventory regards the establishment of national expert panels (specifically, in road transport, land use change and forestry and energy production sectors) which involve, on a voluntary basis, different institutions, local agencies and industrial associations which cooperate for improving activity data and emission factors accuracy.

Specific activities relating to improvements of the inventory and QA/QC carried out in the last year were:

- *Waste Sector Emissions Review.* A revision of emissions from solid waste disposal on land, specifically a study on the average degradable organic carbon on the basis of the waste composition in Italy and on the landfill gas recovery system in Italy has been carried out.
- Solvent and Other Product Use. N<sub>2</sub>O emissions from the use of N<sub>2</sub>O for anaesthesia and from aerosol cans were estimated on account of new information made available from the Italian manufacturers and distributors association of N<sub>2</sub>O products and the Italian Association of Aerosol Producers.
- Energy Balance Verification. The task force of energy and inventory experts (Ministry of Production Activities, ENEA and APAT) established to examine differences in basic data between the CRF and the joint EUROSTAT/IEA/UNECE questionnaire submissions and to improve the details of the National Energy Balance finalised its study and reported the results in the document "Energy data harmonization for CO<sub>2</sub> emission calculations: the Italian case" (ENEA/MAP/APAT, 2004).
- *Road Transport Emissions Review.* The Italian Expert Panel on Transport, which includes experts from Research Institutes, Universities, Industrial Associations, Local Authorities, Ministries and Public Authorities, has continued its work on the improvement and assessment of emission estimations from road transport. Specifically, this year the group was organised in sub-groups according to different subjects of interest. There has been a considerable improvement on the details of basic data to be used within the COPERT model, both in terms of availability and timeliness. Studies of the expert panel group as well as presentations held in different meetings can be found on the website www.inventaria.sinanet.apat.it/ept.
- *MeditAIRaneo Project.* A three years project involving the Inventory Reference Centres of the European Mediterranean Countries (Italy, Spain, France, Greece, Portugal) started at the end of

the year 2000. The aim was to examine in details emissions that are specific and/or typical of the Mediterranean Countries. Four different studies on air emissions from vegetation, agriculture, solvent use and urban road transport in Mediterranean areas were funded by APAT, some of which are still in progress. Common objectives are analysis of methodologies and emission factors used by Mediterranean countries for estimating emissions, individuation of Mediterranean peculiarities, in comparison with other European countries, such as climate, technologies, industrial management, identification of methodological points which need indepth examination and uncertainty assessment. An Italian case study is also planned for each of the four projects. By 2006, all the projects will be concluded and the results will be used in the national inventory to improve country-specific emission factors.

- Data from the Italian Pollutant Emission Register (EPER) from some industrial sectors were used as a check and comparison with the estimates carried out at national level. In particular, this regards the production of non-ferrous metals, chemical productions such as nitric and sulphuric acid, and the production of iron and steel.
- At the national level, a lot of meetings with industry representatives were held in the process of implementing the emission trading directive; this resulted in a better understanding of some processes and the improvement of national emission factors and activity data. Specifically, this was the case of emissions from refineries, production of lime and cement, iron and steel, primary aluminium, bricks and tiles. For these sectors, the first database from the Emission Trading Scheme was analysed.
- *Local inventories*. A study on the top-down approach to the preparation of local inventories was conducted and Italian emissions for different local areas were derived. The results were checked out by regional and local environmental agencies and authorities in order to find out the main weak points and contribute with information available to characterise the local environment, this contributing as well as a feedback to the improvement of the national inventory. Final estimates and the detailed methodologies followed for each SNAP sector to carry out emission figures are published in a technical report (Liburdi et al., 2004).

Further improvements in 2005 will concern: the analysis of sectoral industrial data from the Italian Emission Trading Scheme database, specifically for the iron and steel and cement sectors; on going work jointly with the industrial association to improve  $N_2O$  emission estimates from the solvent and other product use sector; a revision of the factors and parameters for the estimation of CH<sub>4</sub> emissions from enteric fermentation taking into consideration the results from MediterAIRaneo project.

# 1.7 General uncertainty evaluation, including data on the overall uncertainty for the inventory totals

The IPCC Good Practice Guidance (IPCC, 2000) defines the Tier 1 and Tier 2 approaches to estimating uncertainties in national greenhouse gas inventories. At the moment, quantitative estimates of the uncertainties for the Italian GHG inventory are calculated using a Tier 1 approach, which provides a simplified calculation based on the error propagation equations, whilst a Tier 2 approach, corresponding to the application of Monte Carlo analysis, will be applied in the next submissions. With this regard, a specific study on the comparison of different methodologies which can be used to evaluate uncertainty of emissions was finalised (Romano et al., 2004).

The results of the Tier 1 approach are shown in Annex 1. Emission sources are disaggregated into a detailed level and uncertainties are then estimated for these categories.

The Tier 1 approach suggests an uncertainty of 3.2% in the combined GWP total emissions in 2003. The analysis also estimates an uncertainty of 2.4% in the trend between 1990 and 2003.

For the LULUCF sector, the Tier 1 approach has also been applied, which results in a value of uncertainty equal to 71% for the year 2003, whereas the uncertainty for the trend is estimated to be 30%.

## 1.8 General assessment of the completeness

The inventory covers all major sources and sinks, as well as direct and indirect gases, included in the IPCC guidelines.

Table 1.4 summarizes the sectoral coverage of the GHG emissions in the Italian inventory.

CO <sub>2</sub> Emissions from Biomass ALL	М																		

Sectoral and background tables of CRF sheets are complete as far as the details of basic information are available. For instance, for emissions from the military sector, sources are not distinguished between stationary and mobile but only mobile emissions are reported separately; stationary emissions are, on the other hand, included in commercial/institutional sector (1.A.4.a).

As compared to the last year submission,  $CH_4$  emissions from waste incineration both for biogenic and plastics and other non-biogenic waste and  $N_2O$  emissions from other solvent use have been estimated. Potential emissions of PFCs are not estimated because no information on import-export is available at the moment. Multilateral operations emissions are not estimated because no activity data are available.

For fugitive emissions,  $CH_4$  emissions from oil exploration and venting are included in those from oil production because no detailed information is available. Emissions from transport and distribution of oil result as not occurring or negligible.  $CH_4$  emissions from gas exploration are also included in those from production while other leakage emissions are included in distribution emission estimates. Further investigation will be carried out closely with industry about these

figures.  $CH_4$  emissions from gas venting are included with natural gas under 1.B.2.b, production, as not separately supplied by the relevant industries. For industrial processes, emissions from soda ash use are included in glass and paper production emissions because the use of soda is part of that specific production process.

## **Chapter 2 TRENDS IN GREENHOUSE GAS EMISSIONS**

### 2.1 Description and interpretation of emission trends for aggregate greenhouse gas emissions

Summary data of the Italian greenhouse gas emissions for the years 1990-2003 are reported in Annex 7 in Tables A7.1- A7.5.

The emission figures presented are those sent to the UNFCCC Secretariat and to the European Commission in the framework of the Greenhouse Gas Monitoring Mechanism. In agreement with the Convention on Climate Change, the National Greenhouse Gas Inventory is communicated through compilation of the Common Reporting Format.

Total greenhouse gas emissions, in  $CO_2$  equivalent, excluding emissions and removals of  $CO_2$  from land use change, have increased by 11.4% between 1990 and 2003, varying from 511 to 570  $CO_2$ equivalent million tons (Mt), whereas the national Kyoto target is a reduction of 6.5%, as compared the base year levels, by the period 2008-2012.

The most important greenhouse gas,  $CO_2$ , which accounts for 85.5% of total emissions in  $CO_2$  equivalent, shows an increase by 13.2% between 1990 and 2003. In the energy sector, in particular, emissions in 2003 are 13.1% greater than in 1990.

 $CH_4$  and  $N_2O$  emissions are equal, respectively, to 6.1% and 7.4% of the total  $CO_2$  equivalent greenhouse gas emissions.  $CH_4$  emissions have fallen by 9.6% from 1990 to 2003, while  $N_2O$  has increased by 6.1%.

Other greenhouse gases, HFCs, PFCs and SF<sub>6</sub>, range from 0.3% to 1% of total emissions; at present, variations in these gases are not relevant to reaching the emission reduction objectives. Figure 2.1 illustrates the national trend of greenhouse gases for 1990-2003, expressed in  $CO_2$  equivalent terms and by substance;  $CO_2$  emissions do not include emissions and removals from land use change.

Figure 2.1 National greenhouse gas emissions from 1990 to 2003

The share of the different sectors in terms of total emissions remains nearly unvaried over the period 1990-2003. Specifically for the year 2003, the greatest part of the total greenhouse gas emissions is to be attributed to the energy sector, with a percentage of 84%, followed by agriculture and industrial processes, both accounting for 7% of total emissions, waste and use of solvents. Figure 2.2 shows the total greenhouse gas emissions subdivided by sector.

Figure 2.2 Greenhouse gas emissions from 1990 to 2003 by sector

## 2.2 Description and interpretation of emission trends by gas

## 2.2.1 Carbon dioxide emissions

 $CO_2$  emissions, excluding emissions and removals from land use change and forestry, have increased by approximately 13% from 1990 to 2003, ranging from 431 to 487 million tons.

The most relevant emissions derive from the energy industries (33%) and transportation (26%). Manufacturing and construction industries and non-industrial combustion account for 17% each, while the remaining emissions derive from industrial processes (5%) and other sectors (1%). The performance of  $CO_2$  emissions by sector is shown in Figure 2.3.

Figure 2.3 National emissions of CO<sub>2</sub> by sector from 1990 to 2003

The main sectors responsible for the increase of  $CO_2$  emissions are transport and energy industries; in particular, emissions from transport have increased by 24% from 1990 to 2003 while those from energy industries by 19%. Non industrial combustion emissions have increased by 10%, minor increases are also observed for the industrial processes and manufacturing industries and

construction, whereas emissions in the 'Other' sector, mostly fugitive emissions from oil and natural gas and emissions from solvent and other product use, reduced by 24%.

Figure 2.4 illustrates the performance of the following economic and energy indicators:

- Gross Domestic Product (GDP) at market prices as of 1995 (base year 1990=100);
- Total Energy Consumption;
- CO<sub>2</sub> emissions, excluding emissions and removals from land-use change and forests;
- $CO_2$  *intensity*, which represents  $CO_2$  emissions per unit of total energy consumption.

The figures of  $CO_2$  emissions per total energy unit show that  $CO_2$  emissions in the 1990s essentially mirrored energy consumption, with a decoupling between the curves only in recent years, mainly as a result of the substitution of fuels with high carbon contents by methane gas in the production of electric energy and in industry. Nevertheless, this trend stopped since 2000, due to the increase of coal consumption in power plants. In the last year, in spite of the decrease in the GDP level, emissions continue to follow the positive trend.

Figure 2.4 Energy-related and economic indicators and CO<sub>2</sub> emissions

## 2.2.2 Methane emissions

Methane emissions in 2003 represent 6.1% of total greenhouse gases, equal to 34.6 Mt in CO<sub>2</sub> equivalent, and show a decrease of approximately 3 Mt as compared to 1990.

 $CH_4$  emissions are mainly originated from the agricultural sector, which accounts for 47% of total methane emissions, as well as to the management of waste (32.9%) and to energy (19.6%).

Emissions in the agricultural sector regard mainly the breeding of animals and rice cultivation. The agriculture sector shows a decrease of emissions equal to 8.9% compared to 1990.

Activities typically leading to emissions in the waste-management sector are the operation of dumping sites and the treatment of industrial waste-water. The waste sector shows a small decrease in emission levels (-0.4% compared to 1990).

In terms of  $CH_4$  emissions in the energy sector, the reduction (-18%) is the result of two contrasting factors; on the one hand there has been a considerable reduction in emissions caused by leakage from the extraction and distribution of fossil fuels, due to the gradual replacement of natural-gas distribution networks; at the same time, combustion emissions in the road transport sector have increased on account of the overall rise in consumption and, in the civil sector, as the result of increased use of methane in heating systems.

Figure 2.5 shows the emission figures by sector.

Figure 2.5: National CH<sub>4</sub> emissions by sector from 1990 to 2003

## 2.2.3 Nitrous oxide emissions

In 2003 nitrous oxide emissions represent 7.4% of total greenhouse gases, with a growth rate of 6.1% between 1990 and 2003, from 39.9 to 42.4 CO<sub>2</sub> equivalent Mt.

The major source of  $N_2O$  emissions is the agricultural sector (52.9%), in particular the use of both chemical and organic fertilisers in agriculture, as well as the management of waste from the raising of animals. These emissions show a decrease of 1.2% during the period 1990-2003.

Emissions in the energy-use sector (25.6% of the total) show an increase by approximately 27% from 1990 to 2003; this growth can be traced primarily to the road transport sector and is related to the introduction of catalytic converters. However, a high degree of uncertainty still exists with regard to the N<sub>2</sub>O emission factors of catalysed automobiles.

The production of nitric acid, which has decreased in recent years, and of adipic acid, whose levels have grown, account totally for 16.7% of total emissions.

Other emissions in the waste sector primarily regard the processing of industrial and domestic waste-water.

Figure 2.6 shows national emission figures by sector.

Figure 2.6 National  $N_2O$  emissions by sector from 1990 to 2003

### 2.2.4 Fluorinated gas emissions

Italy has set 1995 as the base year for reduction in the emissions of the fluorinated gases covered by the Kyoto Protocol, that's HFCs, PFCs and SF<sub>6</sub>. Taken altogether, the emissions of fluorinated gases represent 7.4% of total greenhouse gases in  $CO_2$  equivalent in 2003, and they show an increase of 245% between 1995 and 2003. This increase is the result of different features for different gases.

HFCs, for instance, have increased considerably from 1995 to 2003, from 0.7 to 4.6  $CO_2$  equivalent Mt. The main sources of emissions are the consumption of HFC-134a, HFC-125, HFC-32 and HFC-143a in refrigeration and air-conditioning devices, together with the use of HFC-134a in pharmaceutical aerosols. Increases during this period are due both to the use of these substances as replacements for gases that destroy the ozone layer and to the greater use of air conditioners in automobiles.

Emissions of PFCs have risen by approximately 47% from 1995 to 2003. The level of these emissions in 2003 is 0.3 Mt in CO<sub>2</sub> equivalent, and it can be traced in equal proportion to the use of the gases in the production of aluminium and in the production of semiconductors. Although the production of PFCs is equal to zero in Italy from the year 1999 onwards, the upward trend shown by the series is due to their consumption and to their use in metal production.

Emissions of  $SF_6$  are equal to 0.5 Mt in  $CO_2$  equivalent in 2003, with a decrease of 19% compared to 1995. Out of the  $SF_6$  emissions, 28% can be traced to the use of gas in magnesium foundries, 60% to the gas contained in electrical equipments. The rest of the emissions results from the gas use in the production of semiconductors. The gas use both in magnesium foundries has been on the rise in recent years, unlike the figures for the gas contained in electrical equipments, which have fallen.

The National Inventory of fluorinated gases has largely improved in terms of the sources and the gases identified. Further in-depth examination and controls are required but higher methods have been applied and some difficulties in procuring activity data from the industry overcome. Nevertheless, uncertainty still regards some activity data which are considered of strategic economic importance and therefore kept confidential.

Figure 2.7 National emissions of fluorinated gases by sector from 1990 to 2003

### 2.3 Description and interpretation of emission trends by source

### 2.3.1 Energy

Emissions in CO<sub>2</sub> equivalent from the energy sector are reported in Table 2.1 and Figure 2.8.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

Table 2.1 Total emissions in CO<sub>2</sub> equivalent from the energy sector by source (1990-2003)

An upward trend is noted from 1990 to 2003. Substances with the highest increase rate are  $CO_2$ , whose levels have increased by 14.2% from 1990 to 2003 and account for 96% of the total, and N<sub>2</sub>O which shows an increase of 22% but its share out of the total is only 2%; CH<sub>4</sub>, on the other hand, shows a decrease of 18.1% from 1990 to 2003 but this is not relevant on total emissions, accounting only for 1%.

Totally emissions from this sector increase by 13.7% from 1990 to 2003.

Details on these figures are described in the specific chapter.

It should be noted that the most significant increase, in terms of total  $CO_2$  equivalent, is observed in the transport and energy industries sectors, about 25% and 19.3%, respectively, from 1990 to 2003; these sectors, altogether, account for more than 60% of total emissions.

Figure 2.8 Trend of total emissions in CO<sub>2</sub> equivalent from the energy sector by gas (1990-2003)

### 2.3.2 Industrial processes

Emission trends from industrial processes are reported in Table 2.2 and Figure 2.9.

Total emission levels, in  $CO_2$  equivalent, show an increase of 19%, from the base year to 2003. Taking into account emissions by substance,  $CO_2$  and  $N_2O$  levels increased by 1% and 5%, respectively; these two substances account altogether for about 86% of the total emissions from industrial processes. A considerable increase is observed in F-gas emissions (245%) and the share of these gases on the total emissions is 14%.

Details for industrial processes emissions can be found in the specific chapter.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

Figure 2.9 Trend of total emissions in CO<sub>2</sub> equivalent from industrial processes by gas (1990-2003)

### 2.3.3 Solvent and other product use

Emissions from the solvent and other product use sector refer to  $CO_2$  and  $N_2O$ , except for gases other than greenhouse.

A considerable amount of emissions from this sector is, in fact, also to be attributed to NMVOC. The share of  $CO_2$  emissions, in this sector, is 59% out of the total; the decrease by 28% from 1990 to 2003 is to be attributed to different sources. Emission levels from paint application sector, which accounts for 52% of total  $CO_2$  emissions from this sector, decreased by 18%; emissions from other use of solvents in related activities, such as domestic solvent use other than painting, printing industries, vehicle dewaxing, which account for 42% of the total, show a decrease of 24%. Finally, emissions from metal decreasing and dry cleaning activities, decreased by 57% but they account for only 6% of the total.

In 2003, solvent use is responsible for 0.3% of the total CO<sub>2</sub> emissions (not considering CO<sub>2</sub> from LUCF) and 37.2% of the total NMVOC emissions, and represents the second source of anthropogenic NMVOC national emissions.

The N<sub>2</sub>O emissions, in 2003, represent about 2% of the total N<sub>2</sub>O national emissions.

The trends of NMVOC,  $CO_2$  and  $N_2O$  emissions are summarised in Table 5.1. Emissions from paint application and other use of solvents for NMVOC and  $CO_2$  are more than 80% and 90% of the total in the sector respectively.

From 1990 to 1995, a constant level of  $N_2O$  emissions is observed, afterwards from 1995 to 1998 emissions increased by 37%. From 1999, there appears to be a reduction in  $N_2O$  emissions, due to a decrease in the anaesthetic use of  $N_2O$ , that has been replaced by halogen gas.

Further details about this sector can be found in the specific chapter.

Figure 2.10 Trend of total emissions in CO<sub>2</sub> equivalent from the solvent and other product use sector (1990-2003)

## 2.3.4 Agriculture

Emissions from the agriculture sector are reported in Table 2.3 and Figure 2.11.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

Table 2.3 Total emissions in CO<sub>2</sub> equivalent from the agricultural sector by source (1990-2003)

Emissions refer to  $CH_4$  and  $N_2O$  levels, which account for 42% and 58% of the total emission of the sector, respectively. The small decrease observed in the total emissions (-5%) is mostly due to the decrease of  $CH_4$  emissions from enteric fermentation (-11%) which account for 28% of the total emissions. Detailed comments can be found in the specific chapter.

Figure 2.11 Trend of total emissions in CO<sub>2</sub> equivalent from agriculture (1990-2003)

### 2.3.5 Waste

Emissions from the waste sector are shown in Table 2.4 and Figure 2.12.

Total emissions in  $CO_2$  equivalent decreased by 5.5% from 1990 to 2003. The decrease is mostly due to the decrease in emissions from waste incineration (-27%), which account for 4% of the total, as well as those from solid waste disposal (-6%) which account for 76%.

Considering emissions by gas, the most important greenhouse gas is  $CH_4$  which accounts for 90% of the total and shows a decrease of 4% from 1990 to 2003. N<sub>2</sub>O levels have increased by 4% while  $CO_2$  decreased by 66%; these gases account for 9% and 1%, respectively. Further details can be found in the specific chapter.

Table 2.5 Total emissions for indirect greenhouse gases and SO<sub>2</sub> (1990-2003)

All gases show a significant reduction in 2003 as compared to 1990 levels. The highest reduction is observed for SO<sub>2</sub> (-72%), CO levels have reduced by 38%, while NO<sub>X</sub> and NMVOC show a decrease by about 35%. A detailed description of the trend by gas and sector as well as the main reduction plans can be found in the Italian National Programme for the progressive reduction of the annual national emissions of SO<sub>2</sub>, NO<sub>X</sub>, NMVOC and NH<sub>3</sub>, as requested by the 2001/81/EC Directive.

The most relevant reductions occurred as a consequence of the Directive 75/716/EC and following European Directives which established maximum levels for sulphur content in liquid fuels and introduced emission standards for combustion installations. As a consequence, in the combustion processes, oil with high sulphur content and coal have been substituted with oil with low sulphur content and natural gas.

Figure 2.13 Trend of total emissions for indirect greenhouse gases and SO<sub>2</sub> (1990-2003)

# Chapter 3: Energy [CRF sector 1]

### **3.1 Introduction**

The aim of this section is to describe in detail the methodology used to estimate the emissions arising from fuel combustion for energy. These sources correspond to IPCC Tables 1A.

Emission inventory is prepared using the energy consumption information available from national statistics and an estimate of the actual use of the fuels. The latter information is available at sectoral level in a great number of publications and it is needed to evaluate emissions of methane and nitrous oxide. Those emissions are related to the actual physical conditions of the combustion process and to environmental conditions.

There is little continuous monitoring of emissions performed in Italy; hence information is rarely available on actual emissions over a specific period of time from an individual emission source. Therefore, the majority of emissions is estimated from other information such as fuel consumption, distance travelled or some other statistical data related to emissions. Estimates for a particular source sector are calculated by applying an emission factor to an appropriate statistic. That is:

Total Emission = Emission Factor x Activity Statistic

Emission factors are typically derived from measurements on a number of representative sources and the resulting factor applied to the whole country.

For certain sectors, emissions data are available for individual sites. Hence the emission for a particular sector can be calculated as the sum of the emissions from these point sources. That is:

Emission =  $\Sigma$  Point Source Emissions

However, it is necessary to carry out an estimate of the fuel consumption associated with these point sources, so that the emissions from non-point sources can be estimated from fuel consumption data without double counting. In general the point source approach is only applied to emissions of indirect greenhouse gases for well defined point sources (eg, power stations, cement kilns, refineries). Direct greenhouse gas emissions and most non-industrial sources are estimated using emission factors.

# 3.2 Key sources

Key source analysis for the 2003 inventory has identified 12 categories with the Tier 2 approach in the energy related emissions.

In the case of the energy sector in Italy a sector by sector analysis instead of a source by source analysis will better illustrate the accuracy and reliability of the emission data, given the interconnection between the underlining data of most key source categories. In Table 3.1 the relevant key sources are listed making reference to the section of the text where they are quoted.

With reference to Table 3.1, half of the key sources (n. 1, 2, 3, 5, 10 and 12) are linked to stationary combustion and to the same set of energy data: to the energy sector CRF table 1.A.1, to the industrial sector, table 1.A.2 and to the civil sector 1.A.4a and .4b. Four out of 6 key sources refer to CO<sub>2</sub> emissions. All those sectors refer to the national energy balance (MAP, 2005 [a]) for the basic energy data and the distribution between various subsectors, even if more accurate data can be found in GRTN database (GRTN, 2005) for the electricity production sector. Evolution of energy consumptions/emissions is linked to the activity data of each sector, refer to para 3.4, 3.5 and 3.7 for the detailed analysis of those sectors. Electricity production is the most "dynamic" sector and most of the emissions increase from 1990 to 2003, for CO<sub>2</sub>, N<sub>2</sub>O and CH<sub>4</sub>, is due to the increase of thermoelectric production, see Tables 3.2, 3.4 and 3.9 for more details.

Another consistent group of four key sources (n. 4, 6, 8 and 9, see Table 3.1) are referred to transport sector, with basic total energy consumption reported in the national energy balance and then subdivided in the different subsectors with activity data taken from various statistical sources. Refer to para 3.6, transport, for an accurate analysis of those key sources. Also this sector shows a remarkable increase in emissions, CO<sub>2</sub>, in particular from air transport and road transport, as can be seen in Table 3.1 and 3.19, respectively. The evolution of N<sub>2</sub>O emissions is linked to technological changes occurred in the period.

Finally, the last group of two key sources refers to oil and gas operations. Also for this sector basic overall production data are reported in the national balance but emissions are calculated with more accurate data published or delivered to APAT by operators, see para 3.11.

 Table 3.1 Energy related key sources and relevant section

### 3.3 Methodology for estimation of emissions from combustion

For the pollutants and sources discussed in this section, emissions result from the combustion of fuel. The activity statistics used to calculate emissions are fuel consumptions provided in the national energy balance ((MAP, 2005 [a])), GRTN (GRTN, 2005) for the power sector and some additional data sources to characterise the technologies used at sectoral level, quoted in the relevant sections.

Emissions are calculated using sector specific spreadsheets according to the equation:

$$E(p,s,f) = A(s,f) \times e(p,s,f)$$

where

E(p,s,f) = Emission of pollutant p from source s from fuel f(kg) A(s,f) = Consumption of fuel f by source s (TJ-t)e(p,s,f) = Emission factor of pollutant p from source s from fuel f (kg/TJ-kg/t)

The pollutants estimated in this way are:

- carbon dioxide (CO<sub>2</sub>)
- NO<sub>x</sub> as nitrogen dioxide
- nitrous oxide (N<sub>2</sub>O)
- methane (CH<sub>4</sub>)
- non methane volatile organic compounds (NMVOC)
- carbon monoxide (CO)
- sulphur dioxide (SO<sub>2</sub>)

The sources covered by this methodology are:

- Electricity (power plants and Industrial producers)
- Refineries (Combustion)
- Chemical and petrochemical industries (Combustion)
- Construction industries (roof tiles, bricks)
- Other industries ( c) metal works factories, food, textiles, others)
- Road Transport
- Coastal Shipping
- Railways
- Aircraft
- Domestic
- Commercial
- Public Service
- Fishing
- Agriculture

The fuels covered are listed in Table 3.2, though not all fuels occur in all sources. Sector specific tables specify the emission factors used.

Emission factors are expressed in terms of kg pollutant/ TJ based on the net calorific value of the fuel.

The carbon factors used are based on national sources and should be appropriate for Italy. Most of the emission factors have been cross checked with the results of specific studies that evaluate the carbon content of the imported/produced fossil fuels at national level. A comparison of the current factors with the IPCC ones was carried out and the results suggest quite limited variations in liquid fuels and some differences in natural gas, explained by basic hydrocarbon composition, and in solid fuels. In case of differences between IPCC and national emission factors the latter have been usually preferred.

The emission factors should apply for all years provided there is no change in the carbon content of fuel over time. There are exceptions to this rule:

- transportation fuels have showed a significant variation around the year 2000 due to the reformulation of gasoline and diesel to comply with the EU directive, see section 3.10 for details;
- the most important imported fuels, natural gas, fuel oil and coal show no negligible variations of carbon content from year to year, due to changes in the origin of imported fuel supply; a methodology has been set up to evaluate annually the carbon content of the average fuel used in Italy, see section 3.10 for details.

The Ministry of Production Activities (Ministero delle Attività Produttive, MAP) publishes annually energy balances (MAP, 2005 [a]) of fuels used in Italy. These balances compare total supply based on production, exports, imports, stock changes and known losses with the total demand. The difference between total supply and demand is reported as 'statistical difference'. In Annex 5 a copy of the 2003 data is attached, the full time series is available on the website https://dgerm.attivitaproduttive.gov.it/dgerm/.

Additionally to fossil fuel, the national energy balance (BEN) reports commercial wood and straw combustion estimates for energy use, biodiesel and biogas. The estimate of GHG emissions are based on these data and on other estimates (ENEA, 2005) for non commercial wood use. Carbon dioxide emissions from biomass combustion are not included in the national total as suggested in

the IPCC Guidelines (IPCC, 1997) but emissions of other GHG gasses and other pollutants are included. CORINAIR methodology (EMEP/CORINAIR, 2001) includes emissions from the combustion of wood in the industrial and domestic sectors as well as the combustion of biomass in agriculture.

The inventory reports also emissions from the combustion of lubricants based on data collected from waste oil recyclers and quoted in the BEN; from 2002 onwards this estimate is included in the column "Refinery feedstocks" raw "Productions", see Annex 5, Table A5.1- National energy balance, year 2003, Primary fuels. These data are not used to calculate emissions, in both reference and sectoral approach.

For most of the combustion source categories, emissions are estimated from fuel consumption data reported in the BEN and an emission factor appropriate to the type of combustion. However the industrial category covers a range of sources and types, so the inventory disaggregates this category into a number of sub-categories, namely:

- Other Industry
- Other Industry Off-road: See paragraph 3.7
- Iron & Steel (Combustion, Blast Furnaces, Sinter Plant): See Annex 4
- Petrochemical industries (Combustion): See Annex 4
- Other combustion with contact industries: glass and tiles: See Annex 4
- Other industries (Metal works factories, food, textiles, others)
- Ammonia Feedstock (natural gas only): See Annex 4
- Ammonia (Combustion) (natural gas only): See Annex 4
- Cement (Combustion ): See Annex 4
- Lime Production (non-decarbonising): See Annex 4

Thus the inventory estimate from fuel consumption emission factors refers to stationary combustion in boilers and heaters. The other categories are estimated by more complex methods discussed in the sections indicated. However, for these processes, where emissions arise from fuel combustion for energy production, these are reported under IPCC Table 1A. The fuel consumption of Other Industry is estimated so that the total fuel consumption of these sources is consistent with BEN.

According to the IPCC 1996 Revised Guidelines (IPCC, 1997), electricity generation by companies primarily for their own use is auto-generation, and the emissions produced should be reported under the industry concerned. However, most national energy statistics (including Italy) report emissions from electricity generation as a separate category. The Italian inventory makes an overall calculation and then attempts to report as far as possible according to the IPCC methodology:

- auto-generators are reported in the relevant industrial sectors of section "1.A.2 Manufacturing Industries and Construction", including sector "1.A.2.f. Other";
- iron and steel auto-generation is included in section 1.A.1c.

Those reports are based on GRTN (GRTN, 2005) estimates of fuel used for steam generation connected with electricity production.

# **3.4 Energy industries**

# **3.4.1 Electricity production**

The source of the data on fuel consumption is the annual report "Statistical data on electricity production and power plants in Italy" ("Dati statistici sugli impianti e la produzione di energia elettrica in Italia"), edited from 1999 by the Italian Independent System Operator (GRTN), a public enterprise that runs the high voltage transmission grid. For the period 1990-1998 the same data were

published by ENEL (ENEL, several years), the former electricity monopoly. The time series is available since 1963.

In these publications the consumptions of all power plants are reported, either public or privately owned. The base data are collected at plant level, on monthly basis. They include electricity production and estimation of physical quantities of fuels and the related energy content; for the bigger installation the energy content is based on laboratory tests. Up to 1999, the fuel consumption was reported at a very detailed level, 17 different fuels, allowing a quite precise estimation of the carbon content. From 2000 onward the published data aggregate all fuels in 5 groups that do not allow for a precise evaluation of the carbon content. In Table 3.2 a copy of the time series 1990-2003 is reported.

For the purpose of calculating GHG emissions, the detailed list of fuels used was delivered to APAT by GRTN for the years 2001, 2002 and 2003; data for the year 2000 are not available. The detailed list is confidential and only the output of the simulation model used to calculate emissions for all years from 2000 to 2003 at the aggregated level of Table 3.2 can be reported (see Annex 2).

At national level other statistics on the fuel used for electricity production do exist, the most remarkable being the National Energy Balance (BEN), published annually. Moreover the UP (Unione Petrolifera, Oil companies association) and ENI, the former national oil company, regularly publish data on this issue. In the past, up to the year 1998, also the association of the industrial electricity producers (UNAPACE) published production data with the associated fuel consumption.

Source: GRTN, 2005

Table 3.2 Time series of power sector production by fuel, kt or 10^6 m<sup>3</sup>

Both BEN and GRTN publications could be used for the inventory preparation, as they are part of the national statistical system and published regularly. The preference, up to date, for GRTN data arises from the following reasons:

- BEN data are prepared on the basis of GRTN reports to IEA, so both data sets come from the same source;
- Before to be published inside BEN, GRTN data are revised to be adapted to the reporting methodology: balance is done on the energy content of fuels and the physical quantities of

fuels are converted to energy using standard conversion factors; so the total energy content of the fuels is the "right" information extracted from the GRTN reports and the physical quantities are changed to avoid discrepancies; the resulting information cannot be cross checked with detailed plant data (collected for the point source evaluation) based on the physical quantities;

- up to the year 1999, the types of fuel used were much more detailed in GRTN database: in BEN the 17 fuels are added up (using energy content) and reported together in 12 categories: emission factors for certain fuels (coal gases or refinery by-products) are quite different and essential information is lost with this process;
- activity data for "BOF converter gas" are not reported in BEN up to 1999, from year 2000 they are added up to the blast furnace gas;
- finally, the two data sets are never the same, even considering the total energy values of fuels or the produced electricity, there are always small differences, less than 1% -see Annex 2 for details- that increase the already sizable discrepancy between the reference approach and the detailed approach.

In Annex 2 there are summary tables where the differences between BEN and ENEL/GRTN data are detailed by primary fuel for four years: 1990, 1995, 1999-2003. The year 1999 is added because in the year 2000 the reported data are quite poor, as already mentioned.

The other two statistical publications quoted before, UP (UP, 2005) and ENI (ENI, 2005), have direct access to fuel consumption data from the associated companies, but both rely on GRTN data for the complete picture. Data from those two sources are used for cross checking and estimation of point source emissions.

To estimate the  $CO_2$  emissions, and also  $N_2O$  and  $CH_4$  emissions, a rather complex calculation sheet is used, see APAT, (APAT, 2003 [a], in Italian) for description. The data sheet summarizes all plants existing in Italy divided by technology, about 60 typologies, and type of fuel used; the calculation sheet can be considered a model of the national power system. For each year, a run estimates the fuel consumed by each plant type, the pollutant emissions and GHG emissions.

The energy data used for the years 1990, 1995, 1999-2003 are reported in Annex 2. The emission factors used are listed in Table 3.7.

The model reports the consumption and GHG emission data according to primary source (oil, coal, natural gas) so that they can be inserted in the CRF. Moreover the model is also able to estimate the energy/emissions data related to the electricity produced and used on site by the main industrial producers. Those data are reported in the industrial sector section, tables 1.A.1.b/c and 1.A.2.

The following Table 3.3 shows an intermediate part of the process, with all energy and emissions summarized by fuel and split in the two main categories of producers: public services and industrial producers for the year 2003. In the period 1990-1997 all the industrial producers energy/emission data were reported in the CRF tables according to the industrial sector (refineries, steel plants, chemical plants and others). From 1998 onwards the expansion of the industrial cogeneration of electricity and the split of the national monopoly has transformed many industrial producers into "independent producers", regularly supplying the national grid. So part of the energy/emissions of the industrial producers are added to table 1.A.1.a.

In Table 3.4 the time series of the total CO<sub>2</sub> emissions deriving from electricity generation activities is reported, including total electricity produced and specific CO<sub>2</sub> emissions for the total production and for the thermoelectric production only. It is clearly showed that although the specific carbon content of the KWh generated in Italy has constantly improved over time the total emissions are growing due to the even bigger increase of electricity production over time. Specific thermoelectric emissions are nearly stable from the year 1999 to 2002 because efficiency increases have been balanced by a growing coal share. In 2003 a remarkable improvement is reported in specific emissions of thermoelectric production, due to the entry into service of more efficient plants, but not in total production due to the reduction of hydroelectric production.

	1990	1995	1999	2000	2001	2002	2003

# **3.4.2 Refineries**

The consumption data used come from BEN (MAP, 2005 [a]), the same data are also reported by UP (UP, 2005).

The available data in BEN specify the quantities of refinery gas, petroleum coke and other liquid fuels. They are reported in Annex 5, Table A5.6.

All the fuel used in boilers and processes, the refinery "losses" and the possible losses of crude oil and all distributed fuels that are due to statistical discrepancies are considered to calculate emissions. Both refinery losses and fuel lost in the distribution network are considered as real but not accounted for in the individual end uses sectors.

Part of refinery losses, flares, are reported in CRF table 1.B.2.a and c, using IPCC emission factors, the other emissions are reported in CRF table 1.A.1.b. From 2002 particular attention has been paid to avoid double counting of the  $CO_2$  emissions checking if the individual refineries report sheets already include losses in the energy balances. It is planned to further investigate this aspect as soon as the new comprehensive reporting requirements of the IPPC directive are routinely used. Additional investigation is also planned to find out the fuel used for steam production, part of which presently seems to be allocated to the general industry.

IPCC Tier 2 emission factors and national emission factors are used, refer to Table 3.7. In Table 3.5 a sample calculation for the year 2003 is reported, with energy and emission data. In Table 3.6 GHG emissions in the years 1990, 1995, 2000-2003 are reported.

# 3.4.3 Manufacture of Solid Fuels and Other Energy Industries

In Italy all the iron and steel plants are integrated, so there is no separated reporting for the different part of the process. A few coke and "manufactured gas" producing plants where existing in the early nineties and they have been reported here. Only one manufactured gas producing plant is still in operation from 2002.

In this section emissions from power plants which use coal gases are also reported. In particular we refer to the electricity generated in the steel plant sites (using coal gases and other fuels).

# 3.5 Manufacturing industries and construction

Energy consumption for this sector is reported in the BEN, reference Annex 5, Tables A5.9 and A5.10, in physical units. The data comprise specification of consumption for 13 sub-sectors and more than 25 fuels. Those very detailed data, combined with industrial production data, allow for a good estimation of all the fuel used by the industrial processes listed in para 3.3, with the exception of coal (see Annex 3). The balance of fuel is assumed as used in boilers and heaters and the emissions are estimated with the emission factors listed in Table 3.7. These factors already contain the correction for the fraction of carbon oxidised (IPCC default values).

Table 3.7 Emission Factors for Power, Industry and Civil sector

# 3.5.1 Estimation of carbon content of coals used in industry

The preliminary use of the CRF software underlined an unbalance of emissions in the solid fuel rows above 20%. A detailed verification pointed out to an already known fact: the combined use of standard IPCC emission factors for coals, national emission factors for coal gases and CORINAIR methodology emission factors for steel works processes produces double counting of emissions.

The main reason for this is the extensive recovery of coal gases from blast furnaces and coke ovens for electricity generation, a specific national circumstance of Italy.

To avoid the double counting a methodology has been developed: it balances energy and carbon content of coking coals used by steelworks, industry, for non energy purposes and coal gasses used for electricity generation. The detailed procedure is described in Annex 3, here we underline that a balance is made between the input coals for coke production and the quantities of derived fuels used in various sectors. The iron and steel sector gets the resulting quantities of energy and carbon after subtraction of what is used for electricity generation, non energy purposes and other industrial sectors.

### 3.5.2 Time series

In the following Table 3.8, GHG emissions connected to the use of fossil fuels, process emissions excluded, in the years 1990, 1995 and 2000-2003 are reported. Industrial emissions do show a remarkable reduction from 1990 to 1995, then the data are more stable, with oscillation connected

to economic cycles. In Table 3.9 the emissions of energy industries (para 3.4), manufacturing industries (para 3.5) and other sectors (para 3.7) are summarized according to key sources categories.

	1990	1995	2000	2001	2002	2003

### **3.6 Transport**

This sector is the one that shows the most pronounced increase in emissions over time, reflecting an increase in fuel consumption.

The mobility demand and particularly the road transportation share have always increased in the time period from 1990 to 2003.

The historical time series of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O emissions is reported in Table 3.10.

The emissions in the table comprise all the emissions reported in table 1.A.3 of CRF.

Emission estimates are discussed below for each sub sector.

Increase in  $N_2O$  emissions is related to the expansion of the car fleet equipped with exhaust gasses catalytic converters.

On the contrary, methane emissions are quite stable, due to the combined effect of technological improvements that limit VOCs from tail pipe and evaporative emissions and the expansion in petrol consumption.

It has to be underlined that in Italy there is a remarkable fleet of motorbikes and mopeds (about 9.1 millions vehicles in 2003) that are using petrol and are not subject to tight VOC emissions control yet.

Table 3.10 GHG emissions for the transport sector

# 3.6.1 Aviation

The IPCC requires the estimation of emissions for 1A3ai International Aviation and 1A3aii Domestic Aviation, including figures both from the cruise phase of the flight and the landing and take-off cycles (LTO). According to the methodologies described in the IPCC Good Practice

Guidance (IPCC, 1997) and in the EMEP/CORINAIR Guidebook (EMEP/CORINAIR, 2001), a method was devised based on the following assumptions and information:

Total inland deliveries of aviation spirit and aviation turbine fuel to air transport are provided in the national energy balance BEN (MAP, 2005 [a]), see Annex 5, Table A5.10. This figure is the best approximation of aviation fuel consumption available and it covers international and domestic but not the split between domestic and international;

Data on annual arrivals and departures of domestic and international landing and (ii) take-off cycles at Italian airports are reported by different sources: National Statistics Institute in the statistics yearbooks (ISTAT, several years), Ministry of Transport in the national transport statistics yearbooks (MINT, 2004) and the Italian civil aviation in the national aviation statistics yearbooks (ENAC/MINT, 2004);

Total consumption for military aviation is given in the petrochemical bulletin (MAP, (iii) 2005 [b]) by fuel. Emissions from military aircraft are reported under 1A5 Other.

Emission factors and consumption factors for LTO cycles and cruise phases are (iv) derived by the EMEP/CORINAIR guidebook (EMEP/CORINAIR, 2001), considering national specificities. These specificities derive from the results of a specific study which, taking into account detailed information on the Italian air fleet and the origin-destination flights for the year 1999, calculated default national values for both domestic and international flights (Romano et al., 1999; ANPA, 2001; Trozzi et al., 2002 [a]) on the basis of the emission and consumption factors reported in the EMEP/CORINAIR guidebook. National average emissions and consumption factors were therefore calculated for LTO cycles and cruise both for domestic and international flights.

To carry out national estimates for greenhouse gases and other pollutants in the Italian inventory, consumptions are calculated for the complete time series using the average consumption factors multiplied by the number of flights for LTO, both domestic and international, and for domestic cruise; on the other hand, consumptions for international cruise are derived by difference from the total fuel consumption reported in the national energy balance and the above estimated values.

The current methodology may overestimate emissions from aircraft for the last years. This is because default factors used pertain to older models and the distribution of the international flights between European and extra-European flights has changed from 1999 with an increase of the shortest distances. Currently the use of a more detailed model for estimating aircraft emissions is under consideration, provided the availability of more data on the flights by national and European civil aviation control authorities.

Data on domestic and international aircraft movements from 1990 to 2003 are shown in Table 3.11 where domestic flights are those entirely within Italy. Emission factors are reported in Table 3.12 and Table 3.13. Total fuel consumptions both domestic and international are reported by LTO and cruise in Table 3.14. GHG domestic emissions from the aviation sector are summarised in Table 3.15. Emissions from international aviation are reported for information only and are not included in national totals.

Military aviation emissions cannot be estimated in this way since LTO data are not available. Therefore emissions are calculated by multiplying military fuel consumption data for the EMEP/CORINAIR default emission factors shown in Table 3.13. These factors are appropriate for military aircrafts.

### 3.6.2 Railways

The electricity used by the railways for electric traction is supplied from the public distribution system, so the emissions arising from its generation are reported under 1A1a Public Electricity.

Emissions from diesel trains are reported under the IPCC category 1A3c Railways. These estimates are based on the gas oil consumption for railways reported in BEN (MAP, 2005 [a]).

Carbon dioxide, sulphur dioxide and  $N_2O$  emissions are calculated on fuel based emission factors using fuel consumption data from BEN. Emissions of CO, NMVOC,  $NO_x$  and methane are based on the EMEP/CORINAIR methodology (EMEP/CORINAIR, 2001). The emission factors shown in Table 3.16 are aggregate factors so that all factors are reported on the common basis of fuel consumption.

Table 3.16 Railway Emission Factors (kt/Mt)

# 3.6.3 Road Transport

Emissions from road transport are calculated either from a combination of total fuel consumption data and fuel properties or from a combination of drive related emission factors and road traffic data.

# **3.6.3.1 Fuel-based emissions**

Emissions of carbon dioxide and sulphur dioxide from road transport are calculated from the consumption of petrol, diesel, LPG and natural gas and the carbon - sulphur content of the fuels consumed. Consumption data for the fuel consumed by road transport in the Italy are taken from the BEN (MAP, 2005 [a]), refer to Annex 5, Tables A5.9 and A5.10, in physical units (rows "III - Road transportation" and "VI - Public Service", subtracting the quantities for military use in diesel oil and off-road uses in petrol).

Emissions of  $CO_2$ , expressed as kg carbon per tonne of fuel, are based on the H/C ratio of the fuel; emissions of  $SO_2$  are based on the sulphur content of the fuel. Values of the fuel-based emission factors for  $CO_2$  from consumption of petrol and diesel fuels are shown in Table 3.17.

Values for  $SO_2$  vary annually as the sulphur-content of fuels change and are shown in UP (UP, 2005). These factors already contain the correction for the fraction of carbon oxidised.

Table 3.17 Fuel-Based Emission Factors for Road Transport

Emissions of  $CO_2$  and  $SO_2$  can be broken down by vehicle type based on estimated fuel consumption factors and traffic data in a manner similar to the traffic-based emissions described below for other pollutants. The 2003 inventory used fuel consumption factors expressed as g fuel per kilometre for each vehicle type and average speed calculated from the emission functions and speed-coefficients provided by COPERT III (EEA, 2000).

Fuel consumption calculated from these functions are shown in Table 3.18 for each vehicle type, emission regulation and road type in Italy. A normalisation procedure was used to ensure that the breakdown of petrol and diesel consumption by each vehicle type calculated on the basis of the fuel consumption factors added up to the BEN figures for total fuel consumption in Italy (adjusted for off-road consumption). Evaporative emissions are not shown in the table.

#### 3.6.3.2 Traffic-based emissions

Emissions of the pollutants NMVOC,  $NO_X$ , CO,  $CH_4$  and  $N_2O$  are calculated from emission factors expressed in grams per kilometre and road traffic statistics estimated by APAT on data released from Ministry of Transport (MINT, 2004). The emission factors are based on experimental measurements of emissions from in-service vehicles of different types driven under test cycles with different average speeds calculated from the emission functions and speed-coefficients provided by COPERT III (EEA, 2000). This source provides emission functions and coefficients relating emission factor (in g/km) to average speed for each vehicle type and Euro emission standard derived by fitting experimental measurements to some polynomial functional form. These functions were then used to calculate emission factor values for each vehicle type and Euro emission standard at each of the average speeds of the road and area types.

The road traffic data used are vehicle kilometre estimates for the different vehicle types and different road classifications in the national road network. These data have to be further broken down by composition of each vehicle fleet in terms of the fraction of diesel- and petrol-fuelled vehicles on the road and in terms of the fraction of vehicles on the road made to the different emission regulations which applied when the vehicle was first registered. These are related to the age profile of the vehicle fleet.

Additional data are required for the estimation of consumption of buses, because the available traffic data seldom distinguish beyond "heavy vehicles". Moreover traffic data on motorcycles are not exhaustive. In both cases the energy consumption is estimated on the basis of the oil companies reports on sold fuels.

It is beyond the scope of this paper to illustrate the COPERT III methodology, in brief the emissions from motor vehicles fall into three different types which are each calculated in a different manner. These are hot exhaust emissions, cold-start emissions and, for NMVOC, evaporative emissions.

Hot exhaust emissions are emissions from the vehicle exhaust when the engine has warmed up to its normal operating temperature. Emissions depend on the type of vehicle, the type of fuel its engine runs on, the driving profile of the vehicle on a journey and the emission regulations which applied when the vehicle was first registered as this defines the type of technology the vehicle is equipped with which effects emissions.

For a particular vehicle, the drive cycle over a journey is the key factor which determines the amount of pollutant emitted.

Key parameters affecting emissions are the acceleration, deceleration, steady speed and idling characteristics of the journey, as well as other factors affecting load on the engine such as road gradient and vehicle weight. However, work has shown that for modelling vehicle emissions for an inventory covering a road network on a national scale, it is sufficient to calculate emissions from emission factors in g/km related to the average speed of the vehicle in the drive cycle (EEA, 2000). Emission factors for average speeds on the road network are then combined with the national road traffic data.

Emissions are calculated from vehicles of the following types:

- Petrol cars
- Diesel cars
- Petrol Light Goods Vehicles (Gross Vehicle Weight (GVW) <= 3.5 tonnes)
- Diesel Light Goods Vehicles (Gross Vehicle Weight (GVW) <= 3.5 tonnes)
- Rigid-axle Heavy Goods Vehicles (GVW > 3.5 tonnes)
- Articulated Heavy Goods Vehicles (GVW > 3.5 tonnes)
- Buses and coaches
- Motorcycles

Detailed data on the national fleet composition can be found in yearly report from ACI (ACI, 2004). In the following Tables 3.20, 3.21 and 3.22 detailed data on the relevant vehicles in the circulating fleet between 1990 and 2003 are reported, subdivided according to the main emission regulations that applied when the vehicle was sold.

Average emission factors are calculated for average speeds on three specified types of roads and combined with the number of vehicle kilometres travelled by each type of vehicle on each of these road types:

- Urban
- Rural
- Motorway

APAT estimates total annual vehicle kilometres for the road network in Italy by vehicle type, see Table 3.23, on the basis of data from various sources:

- Ministry of Transport (MINT, 2004) for rural roads and on other motorway; the latter estimates are based on traffic counts from the rotating census and core census surveys of ANAS;
- highway industrial association for fee-motorway;
- local authorities for built-up areas (urban).

 Table 3.23 Evolution of fleet consistency and mileage

When a vehicle engine is cold it emits at a higher rate than when it has warmed up to its designed operating temperature. This is particularly true for petrol engines and the effect is even more severe for cars fitted with three-way catalysts, as the catalyst does not function properly until the catalyst is also warmed up. Emission factors have been derived for cars and LGVs from tests performed with the engine starting cold and warmed up. The difference between the two measurements can be regarded as an additional cold-start penalty paid on each trip a vehicle is started with the engine (and catalyst) cold.

Evaporative emissions of petrol fuel vapour from the tank and fuel delivery system in vehicles constitute a significant fraction of total NMVOC emissions from road transport. The procedure for estimating evaporative emissions of NMVOCs takes account of changes in ambient temperature and fuel volatility.

# 3.6.4 Navigation

This source category includes all emissions from fuels delivered to water-borne navigation.

Emissions of the Italian inventory from the navigation sector are carried out according to the CORINAIR methodology which provides estimates from Coastal Shipping, Fishing, Naval Shipping and International Marine. Coastal Shipping has been mapped onto 1A3dii National Navigation and Fishing onto 1A4ciii Fishing (EMEP/CORINAIR, 2001).

The emissions reported under Coastal Shipping, Naval Shipping and Fishing are estimated according to the base combustion datasheet using the emission factors given in Table 3.17.

The CORINAIR category International Marine is the same as the IPCC category 1A.3i International Marine. The methodology developed to estimate emissions is based on the following information and assumptions:

- Total deliveries of fuel oil, gas oil and marine diesel oil to marine transport are given in national energy balance (MAP, 2005 [a]) but the split between domestic and international is not provided;
- Naval fuel consumption for inland waterways, ferries connecting mainland to islands and leisure boats, is also reported in the national energy balance;
- Emission factors and consumption factors for national and international traffic derive from the results of a specific study which, taking into account detailed information on the Italian marine fleet and the origin-destination matrix for the year 1999, calculated default national values (ANPA, 2001; Trozzi et al., 2002 [b]) on the basis of emission factors reported in the EMEP/CORINAIR guidebook. National emissions were also divided into harbour activities and national cruise
- National consumptions are estimated using the consumption factors provided by the study whereas consumption for international cruise is derived by difference from the total fuel consumption reported in the national energy balance and the above estimated values.

In Table 3.24 the time series resulting from the above described methodology is shown. The data include the quantities of marine fuels reported by the national energy balance for domestic use, estimate of fuels used in the national harbours or for travel within two Italian destinations and the

resulting bunker fuels used for international travels. Carbon dioxide emissions relevant to the national total are also reported.

Table 3.24 Marine fuel consumptions in domestic and international travels. CO<sub>2</sub> emissions from domestic navigation

Emission estimates from 1A.3i International Marine are reported for information only and are not included in national totals.

# **3.7 Other sectors**

The estimation procedure follows that of the base combustion data sheet, emissions are estimated from the energy consumption data and the emission factor illustrated in Table 3.7.

The category Other sectors comprises emissions from agriculture, fisheries, residential, commercial and others. The national energy balance (refer to Annex 5, Tables A5.9 and A5.10, in physical units, row "DOMESTIC AND COMMERCIAL USES", subtracting the quantities for military use in diesel oil and off-road uses in petrol) does separate energy consumption between civil and agriculture-fisheries, but it does not distinguish between Commercial – Institutional and Residential. The total consumption of each fuel is subdivided on the basis of the estimations reported by ENEA in its annual energy report (ENEA, 2005).

Emissions from 1A.4b Residential and 1A.4c Agriculture/Forestry/Fishing are disaggregated into those arising from stationary combustion and those from off-road vehicles and other machinery. The estimation of emissions from off-road sources is discussed in para 3.7.2. Emissions from fishing vessels are estimated from fuel consumption data (MAP, 2005 [a]) and emission factors are shown in Table 3.7.

# **3.7.1 Other combustion**

Emissions from military aircraft and naval vessels are reported under 1A.5b Mobile. The method of estimation is discussed in para 3.6.1 and 3.6.4.

Emissions from off-road sources are estimated and they are reported under the relevant sectors, i.e. Other Industry, Residential, Agriculture and Other Transport. The methodology of these estimates is discussed in para 3.7.2.

### 3.7.2 Other off-road sources

This category covers emissions from a range of portable or mobile equipment powered by reciprocating diesel or petrol driven engines. They include agricultural equipment such as tractors and combine harvesters; construction equipment such as bulldozers and excavators; domestic lawn mowers; aircraft support equipment; and industrial machines such as portable generators and compressors. In the CORINAIR inventory they are grouped into four main categories (EMEP/CORINAIR, 2001):

- domestic house & garden
- agricultural power units (includes forestry)
- industrial off-road (includes construction and quarrying)
- aircraft support.

Those categories are mapped to the appropriate IPCC classes: Aircraft support is mapped to Other Transport and the other categories map to the off-road vehicle subcategories of Residential, Agriculture and Manufacturing Industries and Construction.

The estimates are calculated using a modification of the methodology given in EMEP/CORINAIR (EMEP/CORINAIR, 2001). This involves the estimation of emissions from around seventy classes of off-road source using the following equation for each class:

$$Ej = Nj \cdot Hj \cdot Pj \cdot Lj \cdot Wj \cdot (1 + Yj \cdot aj / 2) \cdot Ej$$

where

Ej = Emission of pollutant from class j	(kg/y)
Nj = Population of class j.	
Hj = Annual usage of class j	(hours/year)
Pj = Average power rating of class j	(kW)
Lj = Load factor of class j	(-)
Yj = Lifetime of class j	(years)
Wj = Engine design factor of class j	(-)
aj = Age factor of class j	(y-1)
ej = Emission factor of class j	(kg/kWh)

For petrol engined sources, evaporative NMVOC emissions are also estimated as:

$$Evj = Nj \cdot Hj \cdot evj$$

where

Evj = Evaporative emission from class j kg evj = Evaporative emission factor for class j kg/h

The population data have been revised based on a survey of machinery sales (Frustaci, 1999). Machinery lifetime is estimated on the European averages, see EMEP/CORINAIR (EMEP/CORINAIR, 2001), the annual usage data were taken either from industry or published data (EEA, 2000). The emission factors used came mostly from EMEP/CORINAIR and from Samaras (EEA, 2000). The load factors were taken from Samaras (EEA, 2000).

It was possible to calculate fuel consumptions for each class based on fuel consumption factors given in EMEP/CORINAIR (EMEP/CORINAIR, 2001). Comparison with known fuel consumption for certain groups of classes (e.g. agriculture and construction) suggested that the population method overestimated fuel consumption by factors of 2-3, especially for industrial vehicles.

Estimates were derived for fuel consumptions for the years 1990-2003 for each of the main categories:

- A. Agricultural power units: Data on gas oil consumption were taken from ENEA (ENEA, 2005). The consumption of petrol was estimated using the population method for 1995 without correction. Time series is reconstructed in relation to the fuel use in agriculture.
- B. Industrial off-road: The construction component of the gas oil consumption was calculated from the Ministry of Production Activities data (MAP, 2005 [a]) on building and construction. The industrial component of gas oil was estimated from the population approach for 1995. Time series is reconstructed in relation to the fuel use in industry.

C. Domestic house & garden: Petrol and diesel oil consumption were estimated from the EMEP/CORINAIR population approach for 1995. Time series is reconstructed in relation to the fuel use in agriculture.

Emissions from off-road sources are particularly uncertain. The revisions in the population data produced higher fuel consumption estimates. The petrol consumption increased markedly but is still only a tiny proportion of total petrol sales.

# **3.8 International Bunkers**

The methodology used to estimate the quantity of fuels used from international bunkers in aviation and maritime navigation has been illustrated in the relevant transport paragraphs, 3.6.1 and 3.6.4. The methodology implements the IPCC guidelines according to the available statistical data.

# 3.9 Feedstock and non-energy use of fuels

In Table 3.25 and 3.26 detailed data on petrochemical and other non-energy use for the year 2003 are given.

Data are based on a rather detailed yearly report available by MAP. The report summarize answers from a detailed questionnaire that all operator in Italy prepare monthly. The data are more detailed than those normally available by international statistics and refer to:

- input to plants (gross input);
- quantities of fuels returned to the marked (with possibility to estimate the net input);
- fuels used internally for combustion;
- quantities stored in products.

In the energy balances only the input and output quantities from the petrochemical plants are reported, so it may be that the output quantity is greater than the input quantity, due from internal transformation. Therefore it is possible to have negative values for some products mainly gasoline, refinery gas, fuel oil.

With this data it is possible to estimate the quantities of fuels stored in product in percentage on net and gross petrochemical input, see Table 3.25 for details by product and Table 3.27 for the overall figure. The data of Table 3.27 are reported also as a note in CRF table 1.A(d). As can be seen from the value reported for the year 2003 there is a huge difference of the estimated quantities of fuel stored in product if reference is made to "net" or "gross" input. Moreover the estimation of quantities stored in product are quite different from those reported in the Revised 1996 IPCC Guidelines for National GHG Inventories, Reference Manual, ch1, tables 1-5 (IPCC, 1997).

An attempt was made to estimate the quantities stored in products using IPCC percentage values as reported in table 1-5 and the fuels reported as "petrochemical input" in Table 3.25. The resulting estimate of about 7,143 kt of products for the year 2003, is more than 35% bigger than the quantities reported, 5,286 kt, see Table 3.25.

At national level this methodology seems the most precise according to the available data. The European Project "Non Energy use-CO<sub>2</sub> emissions" ENV4-CT98-0776 has analysed our methodology performing a mass balance between input fuels and output products in a sample year. The results of the project confirm the reliability of the reported data (Patel and Tosato, 1997).

With reference to the data of Table 3.26, those non energy products are mainly outputs of refineries. The estimate refers to quantities produced that are reported by manufacturers and summarized by BEN. The data should not be controversial. Minor differences in the overall energy content of those products result if the calculation is based on national data or IPCC default values, see the table for details.

FUEL TYPE	I	Petroch. Input	Returns to refinery/ market	Internal consumption / losses	Quantity stored in products	% on gross input	% on net input	Emission factor (IPCC)

# 3.10 Country specific issues

### 3.10.1 National energy balance

Italian energy statistics are based mainly on BEN, National Energy Balance, that is annually edited by MAP. This report is quite reliable, by international standards, and it may be useful to summarize here its main features:

- it is a balance, every year professional people carry out the exercise balancing final consumption data with import-export information;
- the balance is made on the energy value of energy carriers, taking into account transformations that may occur in the energy industries (refineries, coke plants, electricity production);

- data are collected regularly by the Ministry of Production Activities, on a monthly basis, from industrial subjects;
- oil products, natural gas and electricity used by industry, civil or transport sectors are taxed with excise duties linked to the physical quantities of the energy carriers; those excise duties are differentiated between products and between final consumption sectors (i.e. diesel oil for industrial use pays duties lower than for transportation use and higher than for electricity production; even bunker fuels have a specific registration paper that state that they are sold without excise duties;
- from the point of view of energy consumption information this system produces highly reliable data: BEN is always based on registered quantities of energy consumption, not on estimates; uncertainties may be present in the effective final destination of the product but total quantities are reliable;
- coal is an exception to this rule, it is not subject to excise duties; consumption information are estimates; anyway it is nearly all imported and it is used by a limited number of operators; all of them are monitored on a monthly basis by the Ministry of Production Activities.

# **3.10.2** National emission factors

Monitoring of the carbon content of the fuels used nationally is an ongoing activity at APAT. The principle is to analyse regularly the chemical composition of the used fuel or relevant activity statistics, to estimate the carbon content and the emission factor. National emission factors are reported in Tables 3.7 and 3.17.

The specific procedure followed for each primary fuel (natural gas, oil, coal) is reported in Annex 6.

# 3.11 Fugitive emissions from solid fuels, oil and natural gas

Fugitive emissions in this source category originate from the production and transformation of solid fuels, the production of oil and gas, the transmission and distribution of gas and from oil refining. Trends in fugitive emissions are summarised in Table 3.28.

Totally, fugitive emissions, in  $CO_2$  equivalent, account for 1.5% out of the total emissions in the energy sector. Both  $CH_4$  and  $CO_2$  emissions show a reduction from 1990 to 2003 by 25% and 18%, respectively.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

 Table 3.28 Fugitive emissions from oil and gas 1990-2003 (Gg CO2 eq.)

The results of key source analysis are shown in the following box.

*Key-source identification in the fugitive sector with the IPCC Tier1 and Tier2 approaches* 

1B2	CH <sub>4</sub>	Fugitive emissions from oil and gas operations	Key (L, T)
1B2	$CO_2$	Fugitive emissions from oil and gas operations	Key (L2, T1)

Specifically, methane emissions from oil and gas operations is a key source according to the level and trend assessment both Tier 1 and Tier 2.  $CO_2$  emissions from oil and gas operations is also a key source for the level, Tier 2, and trend assessment, Tier 1. The uncertainty in methane and  $CO_2$  emissions from oil and gas operations is estimated to be 25% as a combination of 3% and 25% for activity data and emission factors, respectively.

Fugitive emissions from solid fuels, reported in 1.B.1, are not relevant. In fact,  $CH_4$  emissions from coal mining refer only to two mines, one underground producing lignite and the other surface producing coal, with very low production in the last ten years;  $CH_4$  emissions from solid fuel transformation refer to the coke production from the iron and steel industry, also decreasing in the last years.  $CO_2$  emissions from 1.B.1 are not occurring. The uncertainty in methane emissions from coal mining and handling is estimated to be 300% as combination of 3% and 300% for activity data and emission factors, respectively.

Fugitive  $CO_2$  emissions reported in 1.B.2 refer to fugitive emissions in refineries during petroleum production processes, such as fluid catalytic cracking, and in flaring.  $CO_2$  emissions from other activities in 1.B.2 do not occur.

CH<sub>4</sub> emissions reported in 1.B.2 derive mainly from the transmission in pipelines and distribution of natural gas and decrease in the last years in account of the gradual substitution of old pipelines.

For the completeness of the CRF tables pertaining to these emissions, in particular 1.B.2, the rationale beyond the values reported and not reported is explained below.

 $CH_4$  fugitive emissions from oil exploration are included in those from production because no detailed information is available. Emissions from transport and distribution of oil result as not occurring or negligible.  $CH_4$  emissions from gas exploration are also included in those from production while other leakage emissions are included in distribution emission estimates. Further investigation will be carried out with industry about these figures.

CH<sub>4</sub> emissions from gas venting are included in production, respectively for oil under 1.B.2.a and natural gas under 1.B.2.b, as not separately supplied by the relevant industries.

A summary of the completeness of CH<sub>4</sub> fugitive emissions is shown in the following Table 3.29.

1.B. 2.a. Oil		
i. Exploration	$CH_4$	Included in 1.B.2.a production
1.B.2.b. Natural Gas	5	
i. Exploration	$CH_4$	Included in 1.B.2.b production
iii. Other leakage	$CH_4$	Included in 1.B.2.b distribution
1.B. 2.c. Venting		
i. Oil	$CH_4$	Included in 1.B.2.a production
ii. Gas	$CH_4$	Included in 1.B.2.b production

 Table 3.29 Completeness of CH4 fugitive emissions

# Chapter 4: INDUSTRIAL PROCESSES [CRF sector 2]

### 4.1 Overview of sector

Included in this category are by-products or fugitive emissions which originate from industrial processes. Where emissions are released simultaneously from the production process and from combustion, as in the cement industry, these are estimated separately and included in category 1A2. All greenhouse gases as well as CO, NO<sub>x</sub>, NMVOC and SO<sub>2</sub> emissions are estimated.

In 2003 industrial processes account for 5.4% of CO<sub>2</sub> emissions, 0.2% of CH<sub>4</sub>, 16.7% of N<sub>2</sub>O, 100% of PFCs, HFCs and SF<sub>6</sub>. In term of CO<sub>2</sub> equivalent, industrial processes share 6.9% of total national greenhouse gas emissions.

The trends of greenhouse gas emissions from the industrial processes sector are summarised in Table 4.1. Emissions are reported in Gg for  $CO_2$ ,  $CH_4$  and  $N_2O$  and in Gg of  $CO_2$  equivalent for F-gases. An increase in HFC emissions is observed from 1990 to 2003, while  $CO_2$  emissions from chemical and metal industry reduced sharply.

Table 4.1 Trend in greenhouse gas emissions from the industrial process sector, 1990-2003

Five key sources have been identified for this sector, for level and trend assessment, using both the Tier 1 and Tier 2 approaches. The results are reported in the following box.

Key-source identification in the industrial processes sector with the IPCC Tier1 and Tier2 approaches

110, 50		en in the matish fair processes sector with the fire of the	and the 2 approaches
2A	$CO_2$	Emissions from cement production	Key (L, T2)
2F	HFC, PFC	Emissions from substitutes for ODS	Key (L, T)
2B	$N_2O$	Emissions from adipic acid	Key (L, T)
2B	$N_2O$	Emissions from nitric acid	Key (T1)
2A	$CO_2$	Emissions from other industrial processes	Key (T1)

 $CO_2$  emissions from cement production are included in category 2A; N<sub>2</sub>O emissions from adipic acid and nitric acid refer both to 2B;  $CO_2$  emissions from other industrial processes include soda ash and glass production (2A), ammonia and other chemical production emissions (2B), aluminium and ferroalloys production (2C); HFC and PFC consumption as substitutes for Ozone Depleting Substances are included in 2F. Methane emissions from the sector are not key sources.

# 4.2 Mineral products (2A)

# 4.2.1. Source category description

In this sector the main source of emissions is  $CO_2$  from cement production (2A1) which is, as already mentioned, a key source and accounts for 3% of the total national emissions.

Limestone and dolomite use accounts for 0.58% of the total national emissions.

 $CO_2$  emissions also occur from processes where lime is produced and account for 0.37% of the total national emissions.

CO<sub>2</sub> emissions from decarbonising in glass production have been estimated and reported in other.

CO<sub>2</sub> emissions from soda ash production are also included in this category.

Asphalt roofing and road paving with asphalt activities contribute only with NMVOC emissions.

# 4.2.2. Methodological issues

IPCC Guidelines and Good Practice Guidance are used to estimate emissions (IPCC, 1997; IPCC, 2000).

Activity data are supplied in the national statistical yearbooks (ISTAT, several years) and by industries. Emission factors are those provided by the IPCC Guidelines (IPCC, 1997; IPCC, 2000), by the EMEP/CORINAIR guidebook (EMEP/CORINAIR, 2001) or by other international Guidebooks (USEPA, 1997).

CO<sub>2</sub> emissions from cement production are estimated by the IPCC Tier 2 approach. Activity data comprise data on clinker production provided by ISTAT (ISTAT, several years). Activity data have been revised from 1990 onwards; the production of hydraulic lime is not included anymore, after a clarification with the Italian Cement Association (AITEC), because it is already accounted for in the clinker production values. Emission factors have also been updated, for the whole time series, taking in account the information provided by the plants and by the Italian Cement Association (AITEC, 2003; AITEC, 2004; AITEC, 2005) in the framework of the European emission registry (EPER) and the European emission trading scheme. In this latter context, all cement production plants reported fuel consumption and emissions, split between combustion process and decarbonising process. The resulting emission factor for cement production is equal to 540 kg CO2/ton clinker, based on the average CaO content in the clinker and taking in account the contribute of carbonates and additives. The emission factor has been suggested to the operators by AITEC (AITEC, 2004) on the basis of a tool provided by the World Business Council for website Sustainable Development and available on the http://www.ghgprotocol.org/standard/tools.htm.

CO<sub>2</sub> emissions from limestone and dolomite use are related to the use of limestone and dolomite in bricks, tiles and ceramic production and iron and steel production. Emission factors are derived by bricks and ceramic industry (ANDIL, 2000; ANDIL, 2004; ASSOPIASTRELLE, 2004; ASSOPIASTRELLE, 2005) and iron and steel association (FEDERACCIAI, 2004) and they have been supplied in the framework of the European emission trading scheme.

 $CO_2$  emissions from soda ash production have been estimated on account of information available on the Solvay process (Solvay, 2003), whereas those from soda ash use are included both in glass and paper production.

CO<sub>2</sub> emissions from lime and glass production and NMVOC emissions from asphalt roofing and road paving have been estimated by production activity data (ISTAT, several years) and default emission factors (IPCC, 1997; EMEP/CORINAIR, 2001).

# 4.2.3. Uncertainty and time-series consistency

The uncertainty in  $CO_2$  emissions from cement, lime, limestone and dolomite use and glass production is estimated to be equal to 10.4% from each activity, as the combination of 3% and 10% for activity data and emission factor, respectively.

The emission trend is related to the production which is stable.

### 4.2.4. Source-specific QA/QC and verification

CO<sub>2</sub> emissions have been checked with the relevant industrial associations.

Both activity data and average emission factors have been compared with data reported in the national EPER registry.

### 4.2.5. Source-specific recalculations

On account of new information available by the relevant industrial associations and by the plants, especially in the framework of the European emission trading scheme, the time series of some activity data and emission factors have been recalculated. Specifically, the recalculation of activity data has regarded the clinker production values. Besides the usual update of data for the last two years, the overall revision of production data has regarded the subtraction of the hydraulic lime produced by cement plants, because already accounted for in the clinker production data. As mentioned above emission factor also has been updated. The time series of activity data and the emission recalculations are shown in Table 4.2.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002

Table 4.2 Production activity data for clinker (kt) and recalculations of CO<sub>2</sub> (Gg) in the cement production sector 1990-2002

 $CO_2$  emission factors for glass and lime production so as for limestone and dolomite use in brick and tiles production have been updated on the basis of production plants information supplied in the framework of the Emission Trading Scheme. For the 2A sector, recalculations results in an increase of emissions for the whole time series from 0,7% in 1990 to 2.3% in 2002. The time series of emissions recalculated are shown in Table 4.3.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002

### 4.2.6. Source-specific planned improvements

Emission factors and activity data will be improved by a detailed sectoral analysis of the national EPER and Emission Trading data for the cement production sector.

# 4.3 Chemical industry (2B)

# 4.3.1. Source category description

CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O emissions from chemical productions are estimated and included in this sector. Emissions from adipic acid production are supplied and referenced by the Italian producer (Radici Chimica, 1993; Radici Chimica, 2005). Specifically, for N<sub>2</sub>O, adipic acid is a key source at level and trend assessment, both with the Tier 1 and Tier 2 approach. These emissions account for 15.2% of total N<sub>2</sub>O emissions in 2003. CO<sub>2</sub> emissions from this source are also estimated and reported in the CRF under other chemical industry.

 $N_2O$  emissions from nitric acid production is also a key source, at trend assessment with the Tier 1 approach. In fact, these emissions show a relevant decrease in the last years as a consequence of the reduction in production.

The sharp decreasing trend of  $CO_2$  emissions from ammonia is the main contributor to the assessment of " $CO_2$  from other Industrial Processes" as a key source for trend with the Tier 1 approach and it is due to the reduction in ammonia production.

The time series of production data related to ammonia, nitric and adipic acids are reported in the following Table 4.4.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
Ammonia	1,455	1,392	1,358	885	612	592	397	446	409	367	414	430	474	578
Nitric acid	1,037	988	937	725	532	588	545	560	480	432	556	527	536	554
Adipic acid	49	54	50	55	55	64	62	62	65	68	71	75	74	69

Table 4.4 Production of ammonia, nitric acid and adipic acid (kt) from 1990 to 2003

### 4.3.2. Methodological issues

Italian production figures and emission estimates for adipic acid have been provided by the process operator (Radici Chimica, 2005) for the whole time series. N<sub>2</sub>O emissions from adipic acid production (2B3) have been estimated using the default IPCC emission factor equal to 0.30 kg N<sub>2</sub>O/kg adipic acid produced because no abatement technology is present on the production plants.

With regard to nitric acid production (2B2), emissions have been recalculated on the basis of a detailed analysis of information reported in the framework of the national EPER registry; production figures are published in the national statistical yearbooks (ISTAT, several years), while the N<sub>2</sub>O emission factors have been calculated from 2001, as a weighted average of EFs supplied by the production plants in the EPER registry. For the years 1990-2000 the default IPCC emission factors for medium pressure plants has been used, and refers to the average emission factor supplied by Norsk Hydro (Norsk Hydro, 2005), equal to 6.75 kg N<sub>2</sub>O/tonne nitric acid. In the '90s, the reduction of N<sub>2</sub>O emissions should be a consequence of the introduction of abatement technology, specifically NSCR, to reduce NO<sub>X</sub> emissions. NO<sub>X</sub> emission factors for nitric acid production have been reduced by more than 70% from 1990 to 2003.

Ammonia production data are published in the international industrial statistical yearbooks (UN, several years) and they have been checked with information reported in the national EPER registry.  $CO_2$  emission factors have been recalculated on the basis of information reported by the production plants for 2002 and 2003 in the framework of the national EPER registry and the value is equal to 1.175 t  $CO_2/t$  ammonia production. This value has been used for the whole time series in consideration that no modifications to the production plants occurred over the period. Natural gas is used as feedstock in the ammonia production plants and the amount of fuel used is included in the energy balance under the no energy final consumption sector (see Annex 5), therefore double counting does not occur.

 $CO_2$  emissions from carbon black production process have been estimated, and reported in the CRF under other chemical industry, on the basis of information supplied by the Italian production plants in the framework of the EPER registry and the European emission trading scheme. Average implied emission factor is equal to 2.33 t  $CO_2/t$  carbon black production.

### 4.3.3. Uncertainty and time-series consistency

The uncertainty in  $N_2O$  emissions from adipic and nitric acid production and in  $CO_2$  emissions from other industrial processes is estimated 10.4%, for each activity, as combination of uncertainties equal to 3% and 10% for activity data and emission factors, respectively.

Adipic acid emission trend are directly related to the production while nitric acid emissions are related to a reduction in production, to the closure of the old technology plants and to the introduction of abatement technology to reduce  $NO_X$  emissions. Adipic acid production is increasing whereas nitric acid production and emissions show a decrease in the last years.

Total CO<sub>2</sub> emissions from chemical production have decreased as a result of a relevant reduction in ammonia production.

# 4.3.4. Source-specific QA/QC and verification

Emissions from adipic, nitric acid, ammonia and other chemical industry production have been checked with the relevant process operators and with data reported to the national EPER registry.

### 4.3.5. Source-specific recalculations

On account of new information available by industry,  $N_2O$  and  $CO_2$  emissions have been recalculated for the whole time series. The recalculation accounts for an increase of 16.1% and 0.1% in  $N_2O$  emissions for 1990 and 2002, respectively; for  $CO_2$  emissions recalculations result in a decrease of 2.3% in 1990 and an increase of 96.2% in 2002. Total recalculation for the chemical industry category (2B) results in the increase of  $CO_2$  equivalent emissions of 10.8% and 5.8% for 1990 and 2002, respectively.

The time series of  $CO_2$  equivalent emission recalculations is reported in Table 4.5.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002
2004 submission													
CO <sub>2</sub> eq. (2B)	8,112	8,413	7,943	7,391	6,770	7,625	7,113	7,230	7,360	7,531	8,040	8,384	8,084
2005 submission													
CO <sub>2</sub> eq. (2B)	8,986	9,268	8,697	8,141	7,477	8,428	7,876	7,998	8,111	8,235	8,874	8,841	8,556
$\Delta$ emissions (%)	10.8	10.2	9.5	10.1	10.4	10.5	10.7	10.6	10.2	9.4	10.4	5.5	5.8

 Table 4.5 Recalculations of CO2 equivalent (Gg) emissions in the cement production sector 1990-2002

### 4.3.6. Source-specific planned improvements

Emission factors and activity data will be improved by collecting more information from the operators about  $N_2O$  emission trends for nitric acid production, especially for the years 1990-2000.

# 4.4 Metal production (2C)

### 4.4.1. Source category description

The sub-sector metal production comprises four sources: "Iron and steel production", "Ferroalloys production", "Aluminium production" and "Magnesium foundries", all identified as non-key sources.

CO<sub>2</sub> emissions from steel production refer to basic oxygen furnaces and electric furnaces.

For the steel production from arc furnaces, the amount of steel recycled is about 15,000 kilotonnes.

 $CO_2$  emissions from pig iron, sinter and coke production are not relevant and by the way they are estimated and included in the combustion processes (1A2a).

CH<sub>4</sub> emissions from steel production are estimated on the basis of emission factors derived from the IPPC "Bref Report" and the EMEP/CORINAIR "Guidebook" and refer to Basic Oxygen furnace, Electric furnaces and Rolling mills. Therefore values are entered in "Other".

CH<sub>4</sub> emissions from coke production are fugitive emissions during solid fuel transformation and have been reported in Table 1B1b of the CRF.

The share of  $CO_2$  emissions from metal production accounts, in the year 2003, for 0.4% of the national total  $CO_2$  emissions, and 6.8% of the total  $CO_2$  from industrial processes.

The share of CH<sub>4</sub> emissions out of the total is not relevant and N<sub>2</sub>O emissions do not occur.

The share of F-gas emissions from metal production out of the national total F-gas levels was 8.9% in the base-year 1995 and less than 5% (0.06% of the national total greenhouse gas emissions) in the year 2003.

### 4.4.2. Methodological issues

CO<sub>2</sub> and CH<sub>4</sub> emissions from the sector have been estimated on the basis of activity data published in the national statistical yearbooks (ISTAT, several years) and industrial reports and emission factors used are those reported in the EMEP/CORINAIR Guidebook (EMEP/CORINAIR, 2001), in sectoral studies (ANPA, 2000; CTN/ACE, 2000) or supplied directly by industry.

CH<sub>4</sub> emissions from steel production, reported in "Other", have been estimated on the basis of emission factors derived from the IPPC specific BREF Report (available at <u>http://eippcb.jrc.es</u>) and the EMEP/CORINAIR Guidebook (EMEP/CORINAIR, 2001) and refer to basic oxygen furnace, electric furnaces and rolling mills.

For the estimation of PFC emissions from aluminium production, both IPCC Tier 1 and Tier 2 methods are used. These emissions, specifically  $CF_4$  and  $C_2F_6$ , have been calculated on the basis of the information provided by the national primary aluminium producer, with reference to the document drawn up by International Aluminium Institute (IAI, 2003) and the IPCC Good Practice Guidance (IPCC, 2000).

The Tier 1 has been used to calculate PFC emissions relating to the entire period 1990-1999. As from the year 2000, the more accurate Tier 2 method has been followed, based on default technology specific slope and overvoltage coefficients.

As concerns the Tier 1 methodology, the emission factors for  $CF_4$  and  $C_2F_6$  were provided, whereas for the Tier 2 site specific values and, where they were not available, default coefficients were provided. In the following tables (Tables 4.6, 4.7, 4.8, 4.9) the EFs and the default parameters used are reported; site specific values are confidential but they have been supplied to the inventory team.

	Technology specific emissions (kg CF <sub>4</sub> / t Al)							
	1990 - 1993	1994 - 1997	1998 - 2000

	1.6	• • • • • • • • • • • • • • • • • • • •	<b>A</b> (1 1 1	1 1 /		

Table 4.9 Coefficients used for estimation with the Tier 2 methodology by plant

At present in Italy there are two primary aluminium production plants, which use a prebake technology with point feeding (CWPB), characterised by low emissions. These plants have been progressively upgraded from a Side Work Prebake technology to Point Fed Prebake technology; three old plants with Side Work Prebake technology and Vertical Stud Søderberg technology stopped operation in 1991 and 1992.

For  $SF_6$  used in magnesium foundries, according to the IPCC Guidelines (IPCC, 1997), emissions are estimated from consumption data made available by the company which operates the only magnesium foundry located in Italy (Magnesium products of Italy, 2005). The plant started its activity in September 1995.

# 4.4.3. Uncertainty and time-series consistency

The combined uncertainty in PFC emissions from primary aluminium production is estimated to be about 11% in annual emissions, 5% and 10% concerning respectively activity data and emission factors; the uncertainty for SF<sub>6</sub> emissions from magnesium foundries is estimated to be about 7%, 5% for both activity data and emission factors.

The uncertainty in  $CO_2$  emissions from the sector is estimated to be 10.4%, for each activity, while for  $CH_4$  emissions about 50%.

In Table 4.10 the emission trend of F-gases per compound from metal production is given.

COMPOUND	1990	1995	1996	1997	1998	1999	2000	2001	2002	2003
CF <sub>4</sub> (PFC-14)	1,289.2	115.6	119.9	122.0	122.8	122.0	168.1	198.1	168.1	234.1

Total F-gas emissions from metal production	1,673.4	143.4	160.6	166.9	176.2	187.2	370.8	684.0	598.7	412.2
TE 11 440 4 4 1 4 4								(1000	0.00	

Table 4.10 Actual emissions of F-gases per compound from metal production in Gg CO<sub>2</sub>eq (1990-2003)

The decreasing of  $SF_6$  consumption in the magnesium foundry in 2003 is due to the abandonment of recycling plant and the optimisation of mixing parameters.

### 4.4.4. Source-specific QA/QC and verification

Emissions from aluminium production are checked with the relevant process operators.

# 4.4.5. Source-specific recalculations

No recalculation has been done.

### 4.4.6. Source-specific planned improvements

The consistency of the PFC emissions from aluminium production will be verified, as two different methodologies have been used on account of the information provided by the industry.

# 4.5 Other production (2D)

# 4.5.1. Source category description

Only indirect gas and SO<sub>2</sub> emissions occur from these sources.

In this sector, non-energy emissions from pulp and paper as well as food and drink production, especially wine and bread, are reported.  $CO_2$  from food and drink production (e.g. gasification of water) can be of biogenic or non-biogenic origin but only information on  $CO_2$  emissions of non-biogenic origin should be reported in the CRF.

According to the information provided by industrial associations,  $CO_2$  emissions do not occur, but only NMVOC emissions originate from these activities.  $CO_2$  emissions from food and beverage included in the previous submissions have been removed since they are originated from sources of carbon that are part of a closed cycle.

As regards the pulp and paper production,  $NO_X$  and NMVOC emissions as well as  $SO_2$  are estimated.

### 4.6 Production of halocarbons and SF<sub>6</sub> (2E)

### 4.6.1. Source category description

The sub-sector production of halocarbons and SF<sub>6</sub> consists of two sources, "HFC-23 emissions from HCFC-22 manufacture" and "Fugitive emissions", identified as non-key sources.

The share of emissions of F-gases from the production of halocarbons and  $SF_6$  in the national total of F-gases was 43.2% in the base-year 1995 and 0.4% in 2003; the share in the national total greenhouse gas emissions was 0.16% in the base-year and 0.005% in 2003.

### 4.6.2. Methodological issues

For source category "HFC-23 emissions from HCFC-22 manufacture", the IPCC Tier 2 method is used, based on plant-level data communicated by the national producer (Solvay-Solexis, 2005); since 1996, data are adjusted for HCFC-22 destruction.

Also for source category "Fugitive emissions", emission estimates are based on plant-level data communicated by the national producer (Solvay-Solexis, 2005).

### 4.6.3. Uncertainty and time-series consistency

The uncertainty in F-gas emissions from production of halocarbons and  $SF_6$  is estimated to be about 11% in annual emissions.

In Table 4.11 an overview of the emissions from production of halocarbons and  $SF_6$  is given for the 1990-2003 period, per compound.

HFC-23 emissions from HCFC-22 had already been drastically reduced in 1988 due to the installation of a thermal afterburner in the plant located in Spinetta Marengo. Productions and emissions from 1990 to 1995 are constant as supplied by industry; from 1996, untreated leaks have been collected and sent to the thermal afterburner, thus allowing reduction of emissions to zero.

PFC and SF<sub>6</sub> emissions are constant from 1990 to 1995 and from 1996 to 1998, reducing to zero from 1999 due to the installation of the thermal afterburner mentioned above. PFC are by-product emissions, whereas SF<sub>6</sub> production stopped from the  $1^{st}$  of January 2005.

As concerns fugitive emissions, emissions of HFC-134a have been cut in 1999 thanks to a rationalisation in the new production facility located in Porto Marghera, whereas HFC-125 and HFC-143 released as by-products from the production of HFC-134a have been recovered and commercialised.

COMPOUND	1990	1995	1996	1997	1998	1999	2000	2001	2002	2003

# 4.7 Consumption of halocarbons and SF<sub>6</sub> (2F)

### 4.7.1. Source category description

The sub-sector consumption of halocarbons and  $SF_6$  consists of three sources, "HFC, PFC emissions from ODS substitutes", key source at level and trend assessment, both Tier 1 and 2 approaches "PFC, HFC,  $SF_6$  emissions from semiconductor manufacturing", "SF<sub>6</sub> emissions from electrical equipment", that are non-key sources. The share of emissions of F-gases from the consumption of halocarbons and  $SF_6$  in the national total of F-gases was 47.9% in the base-year 1995 and 94.6% in 2003; the share in the national total greenhouse gas emissions was 0.17% in the base-year and 1.1% in 2003.

### 4.7.2. Methodological issues

The type of methods used to calculate emissions of F-gases from the consumption of halocarbons and  $SF_6$  are presented in the following box:

Source category	Sub-source	Calculation method
HFC, PFC emissions from ODS substitutes	Refrigeration and air conditioning equipment (2F1)	IPCC Tier 2a
	Foam blowing (2F2)	IPCC Tier 2a
	Fire extinguishers (2F3)	IPCC Tier 2a
	Aerosols/metered dose inhalers (2F4)	IPCC Tier 2a
PFC, HFC, SF <sub>6</sub> emissions from semiconductor manufacturing (2F6)		IPCC Tier 2a
$SF_6$ emissions from electrical equipment (2F7)		IPCC Tier 3c

Sub-sources of F-gas emissions and calculation methods

Basic data have been supplied by industry: specifically, for the air conditioning equipment the national motor company and the agent's union of foreign motor-cars vehicles has provided the yearly consumptions (FIAT, 2005; IVECO, 2005; UNRAE, 2005); pharmaceutical industry has provided aerosols/metered dose inhaler data (AVENTIS, 2005; Boehringer Ingelheim Italia, 2005; Chiesi Farmaceutici, 2005; GSK, 2005; LUSOFARMACO, 2005; Menarini, 2005); the semiconductor manufacturing industry has supplied consumption data for four national plants (ST Microelectronics, 2005; MICRON, 2005); finally, for the sub-source fire extinguishers, the

European Association for Responsible Use of HFCs in Fire Fighting have been contacted (ASSURE, 2005).

 $SF_6$  emissions from electrical equipment from 1990 to 1994 have been estimated according to IPCC Tier 2a approach.  $SF_6$  leaks from installed equipment have been estimated on the basis of the total amount of sulphur hexafluoride accumulated and of average leakage rates; leakage data published in environmental reports have also been used for major electricity producers (ANIE, 2005).

IPCC Tier 1a method has been used to calculate potential emissions, using production, import, export and destruction data provided by the national producer (ANIE, 2005).

#### 4.7.3. Uncertainty and time-series consistency

The combined uncertainty in F-gas emissions from HFC, PFC emissions from ODS substitutes and PFC, HFC, SF<sub>6</sub> emissions from semiconductor manufacturing is estimated to be about 58% in annual emissions, 30% and 50% concerning respectively activity data and emission factors; the uncertainty in SF<sub>6</sub> emissions from electrical equipment is estimated to be 11.1% in annual emissions, 5% and 10% concerning respectively activity data and emission factors.

In Table 4.12 an overview of the emissions from consumption of halocarbons and  $SF_6$  is given for the 1990-2003 period, per compound. In Table 4.13 an overview of the potential emissions is given for the 1990-2003 period, per compound. Concerning PCF potential emissions, there is no information on import/export, whereas the production is zero (Solvay-Solexis, 2005).

consumption of halocarbons and SF<sub>6</sub>

Table 4.14 Comparison between recalculated and previous F-gas emissions from the consumption of halocarbons and SF<sub>6</sub> per gas in percentage (1990-2002)

As concern HFC-134, a double counting has been corrected; HFC-134 emissions reported in previous submissions for truck's air conditioning equipment were already included in HFC-134a emissions communicated by the national industry IVECO.

The differences for 2002 for  $SF_6$  emissions from electrical equipment and HFC-134a from air conditioning system are due to an erroneous calculation referring to the last submission.

The most relevant recalculation, in terms of emission, concern HFC-227ea from fire extinguishers, where the EF has been corrected.

# Chapter 5: SOLVENT AND OTHER PRODUCT USE [CRF sector 3]

### 5.1 Overview of sector

In this sector all non-combustion emissions from other industrial sectors than the manufacturing and energy industry are reported. The indirect  $CO_2$  emissions, related to Non-Methane Volatile Organic Compound (NMVOC) emissions from solvent use in paint application, degreasing and dry cleaning, chemical products manufacturing or processing and other use, have been estimated.

 $N_2O$  emissions have been included in the submission of this year. These emissions arise from the use of  $N_2O$  in medical applications, such as anaesthesia, and in food industry, where  $N_2O$  is used as a propelling agent in aerosol cans, specifically those used for whipped cream. The entire time series from 1990 to 2003 has been reconstructed.

In 2003, solvent use is responsible for 0.3% of the total CO<sub>2</sub> emissions (not considering CO<sub>2</sub> from LUCF) and 37.2% of total NMVOC emissions, and represents the second source of anthropogenic NMVOC national emissions.

N<sub>2</sub>O emissions, in 2003, represent about 2% of the total N<sub>2</sub>O national emissions.

The trends of NMVOC,  $CO_2$  and  $N_2O$  emissions are summarised in Table 5.1. Emissions from paint application and other use of solvents for NMVOC and  $CO_2$  are more than 80% and 90%, respectively, of the total in the sector.

From 1990 to 1995, a constant level of  $N_2O$  emissions is observed, afterwards from 1995 to 1998 emissions increased by 37%. From 1999, there appears to be a reduction in  $N_2O$  emissions, due to a decrease in the anaesthetic use of  $N_2O$ , that has been replaced by halogen gas.

Table 5.1 Trend in NMVOC, CO<sub>2</sub> and N<sub>2</sub>O emissions from the solvent use sector 1990-2003 (Gg)

 $CO_2$  emissions from solvent use is a key source in the Tier 2 analysis both for level and trend assessment, especially because of the high level of uncertainty in the estimates and a strong reduction of emissions in these years. On the other hand, N<sub>2</sub>O emissions from solvent use is a key source in the Tier 2 analysis for trend assessment, especially because of the high level of uncertainty in the activity data and the increase of emission levels. The results are reported in the following box. Key-source identification for solvent and other use with the IPCC Tier1 and Tier2 approaches

3A-3D	$CO_2$	Indirect emissions from solvent use and other product use	Key (L2, T2)
3D	N <sub>2</sub> O	Emissions from uses of N2O in anaesthesia and aerosol cans	Key (T2)

## 5.2 Source category description

In accordance with the indications of the IPCC Guidelines (IPCC, 1997), the carbon contained in oil-based solvents, or released from these products, has been considered both as NMVOC and  $CO_2$  emissions as final oxidation of NMVOC. Emissions from the following sub-sectors are estimated: solvent use in paint application (3A), degreasing and dry cleaning (3B), manufacture and processing of chemical products (3C), other solvent use, such as printing industry, glues application, use of domestic products (3D).

 $CO_2$  emissions have been estimated and included in this sector as they are not already accounted for in the energy and industrial processes sectors.

 $N_2O$  emissions from the use of  $N_2O$  for anaesthesia and from aerosol cans (3D) have been estimated. Emissions of  $N_2O$  from fire extinguishers do not occur.

Emissions of  $N_2O$  from other use of  $N_2O$  (3D) have not been estimated because no information on activity data and emission factors is available at present.

### **5.3 Methodological issues**

Emissions of NMVOC from solvent use have been estimated according to the CORINAIR methodology with a bottom-up approach, applying both national and international emission factors (Vetrella, 1994; EMEP/CORINAIR, 2001). All the activities in the Selected Nomenclature for Air Pollutant classification (SNAP97) have been estimated.

Country specific emission factors provided by several accredited sources have been used extensively, in particular for paint application (Professione Verniciatore del Legno, several years; GRUPPO FIAT, 2004), solvent use in dry cleaning (ENEA/USLRMA, 1995), solvent use in textile finishing and in the tanning industries (TECHNE, 1998). Basic information from industry on percentage reduction of solvent content in paints and other products has been applied to EMEP/CORINAIR emission factors in order to evaluate the reduction in emissions during the considered period.

The conversion of NMVOC emissions into  $CO_2$  emissions has been carried out considering specific factor calculated on the basis of molecular weights and suggested by the European Environmental Agency for the CORINAIR project (EEA, 1997), except for emissions from the 3C sub-sector to avoid double-counting as suggested in the Common Reporting Format.

Emissions of  $N_2O$  have been estimated taking into account information made available by industrial associations. Specifically, the manufacturers and distributors association of  $N_2O$  products has supplied data on the use of  $N_2O$  for anaesthesia from 1994 to 2003 (ASSOGASTECNICI, 2005). For previous years, data have been estimated by the number of surgical beds published by national statistics (ISTAT, several years). The Italian Association of Aerosol Producers (AIA – ASSOCIAZIONE ITALIANA AEROSOL [a] and [b], 2005) has provided data on the annual production of aerosol cans.

It is assumed that all of  $N_2O$  used will eventually be released to the atmosphere, therefore the emission factor for anaesthesia is 1 Mg  $N_2O/Mg$  product use, while the emission factor used for aerosol cans is 0.025 Mg  $N_2O/Mg$  product use, because the  $N_2O$  content in aerosol cans is assumed to be 2.5% on average (Co.Da.P., 2005).

 $N_2O$  emissions have been calculated multiplying activity data, total quantity of  $N_2O$  used for anaesthesia and total aerosol cans products, by the related emission factors.

# 5.4 Uncertainty and time-series consistency

The combined uncertainty in  $CO_2$  emissions from solvent use is estimated equal to 58% due to an uncertainty by 30% and 50% in activity data and emission factors, respectively. For N<sub>2</sub>O emissions, the uncertainty is estimated equal to 51% due to an uncertainty in activity data of N<sub>2</sub>O use of 50% and 10% in the emission factors.

The decrease in NMVOC emission levels from 1990 to 2003 is about 20% due to the reduction of emissions especially in degreasing and dry cleaning and in other use of solvents. The European Directive (EC, 1999) regarding NMVOC emission reduction in this sector entered into force in Italy in January 2004, establishing a reduction of the solvent content in products. Figure 5.1 shows emission trends from 1991 to 2003 with respect to 1990 by sub-sectors.

From 1990 to 2003, emissions from the use of  $N_2O$  increased by about 8%.

Figure 5.1 Trend of NMVOC emissions from 1991 to 2003 as compared to 1990 (%)

# 5.5 Source-specific QA/QC and verification

In 2003, data production and consumption time series for some activities (paint application in constructions and buildings, polyester processing, polyurethane processing, pharmaceutical products, paints manufacturing, glues manufacturing, textile finishing, leather tanning, fat edible and non edible oil extraction, application of glues and adhesives) have been updated with data acquired by the National Statistics Institute (ISTAT [a], [b], [c], several years), industrial associations (AVISA, 2005) and international organization (FAO, several years).

In the framework of the MeditAiraneo project, APAT commissioned to the Techne Consulting a survey to collect national information on emission factors in the solvent sector. The results, published in the report "Rassegna dei fattori di emissione nazionali ed internazionali relativamente al settore solventi" (TECHNE, 2004), have been used to verify and validate the emission estimates.

In this year submission moreover,  $N_2O$  emissions from the use of this gas in anaesthesia application and in aerosol cans have been estimated.

#### 5.6 Source-specific recalculations

Source-specific recalculations are equal, on average, to 3% of the total NMVOC levels in the sector. Specifically, for the years 1997-2002, there has been a revision of emissions from fat edible and non edible oil extraction and application of glues and adhesives. In general, the higher level is due to the updating of activity data time series.

The recalculation for  $CO_2$  and  $N_2O$  emission levels, in terms of  $CO_2$  equivalent, is high and, on average, equal to 64% because  $N_2O$  emissions have been estimated and reported in this year submission.

Gas	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002

#### 5.7 Source-specific planned improvements

A revision of emission factors and activity data on the basis of information by industrial associations for some activities, such as domestic solvent use, will be carried out.

# Chapter 6: AGRICULTURE [CRF sector 4]

## 6.1 Overview of sector

The agriculture sector in the Italian inventory includes five source categories: enteric fermentation (4A), manure management (4B), rice cultivation (4C), agriculture soils (4D) and field burning of agriculture residues (4F) and the estimation of methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O). Savannas areas (4E) are not present in Italy. Emissions from other sources (4G) have not been estimated.  $CO_2$  and F-gas emissions do not occur.

In 2003, the agriculture sector has been the dominant national source for methane and nitrous oxide emissions, accounting for 47.8% (777.47 Gg CH<sub>4</sub>) and 54.1% (72.32 Gg N<sub>2</sub>O) of total national emissions, respectively. Emission trends for the agriculture sector, for methane and nitrous oxide gases, expressed in Gg, are summarised in Table 6.1. Methane emissions from enteric fermentation and nitrous oxide emissions from direct agriculture soils are the most relevant source categories in this sector; and their individual share in national total greenhouse gas emissions, in  $CO_2$  equivalent, is 1.9% and 2.9%, respectively.

Table 6.1 Trend in greenhouse gas emissions from the agriculture sector, 1990-2003 (Gg)

In 2003, methane emissions from enteric fermentation and nitrous oxide from agricultural soils, both direct and indirect emissions, are ranked among the top-10 level key sources; methane emissions from enteric fermentation are also ranked among the top-10 trend key sources.

In the following box, according to a level and/or trend assessment (*IPCC Tier 1 and Tier 2 approaches*), key and non-key sources from the agriculture sector are shown. Methane emissions from enteric fermentation, manure management and rice cultivation, as well as nitrous oxide emissions from manure management and agricultural soils, direct, indirect and from animal production, have been identified as key sources.

Key-source identification in the agriculture sector with the IPCC Tier1 and Tier2 approaches

As emission factors and activity data are the main parameters for the calculation of emissions, there are some general aspects, which are important to be mentioned. In general, emission factors used for the estimation of emissions in agriculture reflect specific national characteristics, in some cases also IPCC default emission factors have been used. Improvements in estimations are due to more detailed information on activity data or parameters available from the national agriculture statistics. By the time of the preparation of the emission inventory, some activity data for 2003 were not available, therefore estimations have been carried out on the basis of times series; these data will be updated in the next submission. Recommendations from the Centralized Review have been taken into consideration (FCCC/WEB/IRI/2004/ITA<sup>1</sup>).

# **6.2.** Enteric fermentation (4A)

#### 6.2.1. Source category description

As mentioned previously, methane emissions from enteric fermentation is a major key source, both in terms of level and trend for Tier 1 and Tier 2 approaches.

In 2003, methane emissions from enteric fermentation were 520.63 Gg, which represent 67% of methane emissions for the agriculture sector (68.9% in 1990) and 31.6% for total methane emissions (32.2% in 1990). Methane emissions from this source mainly consist of cattle emissions, with 189.83 Gg for dairy cattle and 228.71 Gg for non-dairy cattle, representing 36.5% (42.3% in 1990) and 43.9% (40.6% in 1990) of enteric fermentation, respectively.

For enteric fermentation, all livestock categories have been estimated except camels and llamas, which are not present in Italy; methane emissions from poultry do not occur and emissions from rabbits are estimated and included in "Other" as suggested by IPCC guidelines.

#### 6.2.2. Methodological issues

Methane emissions from enteric fermentation are estimated by defining an emission factor for each livestock category multiplied by the population of the same category. Data for each livestock category are collected from the National Institute of Statistics (ISTAT, several years [a], [b], [c], [g], [h]), and are based on specific national surveys (milk production<sup>2</sup>, farm structure and production<sup>3</sup>), and from a general agriculture census carried out each 10 years (ISTAT, 2000).

All livestock categories provided by ISTAT are classified according to the type of production, slaughter or breeding, and the age of animals. Only for rabbits, activity data for 1990 have been collected from ISTAT agriculture census, and for the years 1991-2003, activity data from brood-rabbits and other rabbits have been reconstructed on the basis of meat production.

Methane emissions from enteric fermentation for dairy cattle are estimated using Tier 2 approach, as suggested in the Good Practice Guidance (IPCC, 2000).

Parameters used for the calculation of time series emission factors are presented in the following box.

<sup>&</sup>lt;sup>1</sup> Italy, Report of the Individual review of the GHG Inventory submitted in the year 2004 – Agriculture sector (4 March 2005)

<sup>&</sup>lt;sup>2</sup> Indagine annuale sul settore lattiero-caseraio, survey done each year to industries that treat and transforms milk (dairy factories, milk centres and centres for the collection of milk).

<sup>&</sup>lt;sup>3</sup> Indagine sulla struttura e produzione delle aziende agricole, survey done each two years in agricultural farms.

Parameters	Value	Reference
Average weight (kg)	650	CRPA, 2000
Coefficient NEm (dairy cattle)	0,335	NRC, 2001; IPCC, 2000
Pasture (%)	10	CRPA, 2000
Weight gain (kg/day)	0,051	CRPA, 2004 [b]
Fat content in milk (%)	3.59-3.71	ISTAT, several years [a], [b], [d], [e]
Hours of work per day	0	CRPA, 2000
Portion of cows giving birth	0.92-0.98	AIA, 2001
Milk production (kg/head/day)	13.4-17.4	ISTAT, several years [a], [b], [c] [d], [e], [h]
Digestibility of feed (%)	65	CRPA, 2004 [b]
Methane conversion rate (%)	5.2-5.5	CRPA, 2000
MJ/kg methane	55.65	IPCC, 2000

Parameters for the calculation	n of dairy cattle emission	n factors from enteric fermenta	tion
--------------------------------	----------------------------	---------------------------------	------

During the years, variation of dairy cattle emission factor has been attributed to new or updated specific national parameters, such as fat content in milk, portion of cows giving birth, milk production and methane conversion factor; parameters and feeding characteristics are described in national publications (CRPA, 2004[a]). In particular, average milk production yield is composed by milk used for dairy production and consumption (*latte munto*<sup>4</sup>) and milk used for calves feeding (*alimentazione dei bestiami poppato dai redi-mammella*<sup>5</sup>); their contribution to national milk production fluctuates during the years. An in depth review of different statistical sources for the milk production (OSSLATTE, 2001; OSSLATTE/ISMEA, 2002; OSSLATTE/ISMEA, 2003; AIA/ISMEA/OSSLATTE, 2003; OSSLATTE/ISMEA, 2004) has been done. The methane conversion rate, based on the energetic concentration of the ration, is progressively reduced, according to expert judgement, due to an increase of efficiency on ingested food (CRPA, 2000). Data for fat content of milk, portion of cows giving birth, milk production and methane conversion factor are presented in Table 6.2.

	Fat content in milk (%)	Portion of cows giving birth	Methane conversion rate (%)	Milk production yield (kg/head/d)
1990	3.59	0.98	5.5%	13.38
1991	3.59	0.97	5.5%	14.87
1992	3.59	0.96	5.5%	15.91
1993	3.63	0.96	5.5%	15.70
1994	3.64	0.96	5.4%	16.57
1995	3.64	0.94	5.4%	16.76
1996	3.65	0.95	5.3%	17.24
1997	3.66	0.94	5.3%	17.43
1998	3.71	0.93	5.3%	17.34
1999	3.69	0.92	5.2%	17.28
2000	3.65	0.93	5.2%	17.39
2001	3.65	0.92	5.2%	16.55
2002	3.65	0.92	5.2%	16.18
2003	3.65	0.92	5.2%	16.99

Table 6.2 Parameters used for the estimation of CH<sub>4</sub> enteric fermentation emissions for dairy cattle, 1990-2003

Resulting dairy cattle emission factors (EF) are presented in Table 6.5. In 2003, EF was estimated to be 99.86 kg CH<sub>4</sub>/head/year; EF proposed by the IPCC is equal to 100 kg CH<sub>4</sub>/head/year (IPCC, 1997).

<sup>&</sup>lt;sup>4</sup> latte munto, composed of milk delivered to dairy factories, direct sales, farm cheese, home consumption and feed

<sup>&</sup>lt;sup>5</sup> alimentazione dei bestiami poppato dai redi-mammella, milk which is suckled from calves.

For non-dairy cattle, methane emissions from enteric fermentation are estimated with Tier 2 approach (IPCC, 2000), defining emission factors with country-specific data. Emission factors are estimated for disaggregated livestock categories, as shown in Table 6.3, and are based on dry matter intake (kg/head/day) calculated as percentage of live weight (INRA, 1988; NRC, 1984; NRC, 1988; Borgioli, 1981; Holter and Young, 1992; Sauvant, 1995; CRPA, 2000). Dry matter intake is converted to gross energy (MJ/head/day) using 18.45 MJ/kg dry matter (IPCC, 2000). Emission factors for each category have been calculated by using equation 4.14 from the Good Practice Guidance (IPCC, 2000). Parameters used for the estimation of non-dairy cattle emission factor are shown in Table 6.4.

National characteristics of Italian breeding are reflected in emission factors and are related to the classification age of the animals and dry matter intake. Implied non-dairy cattle emission factors are presented in Table 6.5. They include all cattle categories except for dairy cattle. In 2003, emission factor was estimated to be 48.35 kg CH<sub>4</sub>/head/year; EF proposed by IPCC is 48 kg CH<sub>4</sub>/head/year (IPCC, 1997).

Table 6.4 Main parameters for non-dairy cattle CH<sub>4</sub> emission estimations, 1990-2003

A tier 1 approach using IPCC default emission factors was used to estimate methane emissions from swine, sheep, goats, horses, mules and asses (IPCC, 1997). According, to country specific characteristics in Italy, rabbits have also been considered; methane emissions from rabbits were estimated using a country-specific emission factor suggested by the Research Centre on Animal Production (*Centro Ricerche Produzioni Animali*, CRPA). Daily dry matter intake for brood-rabbits and rabbits are 0.13 kg/day and 0.11 kg/day, respectively, and it has been assumed 0.6% as methane conversion rate (CRPA, 2004[c]).

Emission factors from 1990 to 2003 for all livestock categories, dairy cattle, non-dairy cattle, buffalo, swine, sheep, goats, horses, mules and asses, and other (rabbit) are presented in Table 6.5.

Year	Dairy cattle	Non-dairy cattle	Buffalo	Sheep	Goat	Horses	Mules and asses	Swine	Other: Rabbit

Table 6.5 Average methane emission factors for enteric fermentation (kg CH<sub>4</sub>/head/yr), 1990-2003

#### 6.2.3. Uncertainty and time-series consistency

Uncertainty of methane emissions from enteric fermentation is estimated to be 28% for annual emissions, as a combination of 20% of uncertainty for both activity data and emission factors.

In 2003, livestock methane emissions from enteric fermentation were 11.4% (520.63 Gg) lower than in 1990 (587.68 Gg) while from 1990 to 2003 dairy cattle livestock have decreased by 28%, from 2,600,000 to 1,900,000, and non-dairy cattle by 7%, from 5,100,000 to 4,700,000. The decrease in cattle number is tending to drive down livestock emissions, particularly as emissions per head from cattle are 10 times that per head of sheep or goat. Additionally, cattle contributes with 79-84% to the total methane emissions in this category, sheep with 11-15% and the rest of livestock categories with 5-7%. In Table 6.6, enteric fermentation methane emission trends from 1990 to 2003 are presented.

Year	Dairy cattle	Non-dairy cattle	Buffalo	Sheep	Goats	Horse	Other equines	Sows	Other swine	Rabbit	TOTAL

### 6.2.4. Source-specific QA/QC and verification

Specific activities from the MeditAIRanean project for the agriculture sector are mainly focused on the assessment of critical points and uncertainties, evaluation of basic activity data and emission factors. The project is considering specific peculiarities of the European Mediterranean Region taking into account parameters for the calculation of emissions such as climate, technologies, industrial management, livestock breeding, etc. Currently, the project has started with an in depth analysis of emission factors and methodologies of categories with higher contribution of emissions in the agriculture sector (Valli et al., 2004). The work is still in progress and results will be used for the future submissions.

# 6.2.5. Source-specific recalculations

Recalculations in the dairy cattle category are due to the update of parameters used for the estimation of the emission factor. These parameters are: weight gain, fat content of milk, portion of cows giving birth, milk production, digestibility of feed and methane conversion rate (see Table 6.2).

In Table 6.7 new and old dairy cattle emission factors from 2004 and 2005 submissions are presented.

The new emission factors are higher from 3% to 17% than those used in the previous submission.

#### 6.2.6. Source-specific planned improvements

In the framework of MeditAIRanean project, further inputs are expected for future submissions.

Year	Emission factor 2004 submission	Emission factor 2005 submission
1990	88.72	94.11
1991	95.60	98.74
1992	95.36	101.96
1993	91.32	101.55

### 6.3. Manure management (4B)

#### 6.3.1 Source category description

As mentioned above, methane and nitrous oxide emissions from manure management are key sources. Methane emissions are key source at level and trend assessment, both Tier 1 and Tier 2, while nitrous oxide emissions are key sources at level, both Tier 1 and Tier 2, and Tier 2 trend assessment.

In 2003, methane emissions from manure management were 181.94 Gg, which represents 23.4% of methane emissions for the agriculture sector (22.5% in 1990) and 11% for total methane emissions (10.5% in 1990). Methane emissions from this source mainly consist of cattle, equal to 88.32 Gg, and swine emissions, 70.68 Gg, which represent 48.5% (55.1% in 1990) and 38.8% (35.1% in 1990) of manure management methane emissions, respectively.

In 2003, nitrous oxide emissions from manure management were 12.81 Gg, which represents 17.7% of N<sub>2</sub>O emissions for the agriculture sector (16.9% in 1990) and 9.4% for total nitrous oxide emissions (9.6% in 1990). Nitrous oxide emissions from this source mainly consist of the solid storage source with 11.52 Gg, which accounts for 90% of manure management emissions.

#### 6.3.2. Methodological issues

Methane emission factors for manure management have been calculated for cattle, buffalo and swine with IPCC Tier 2 approach. Cattle and buffalo emission factors have been calculated for the years 1990 and 1995 at regional level and on a monthly basis as described below and indicated as Method 1. For later years, average emission factors calculated on a regional basis have been used and applied to the whole time series with a simplified methodology (Method 2).

For all livestock categories, as mentioned before (section 6.2.2) activity data have been collected from ISTAT. For the specific case of rabbit, activity data have been reconstructed on the basis of a livestock production index.

# Methane emissions (cattle and buffalo) Method 1: Regional basis

Estimates of methane emissions from manure management, drawn up on a regional basis, depend on the specific manure management practices and environmental conditions (Safley et al., 1992; Steed and Hashimoto, 1995; Husted, 1994), specifically on the following factors: average regional monthly temperatures (UCEA, 2005), amount of slurry and solid manure produced per livestock category (CRPA, 1993) and management techniques for the application of slurry and solid manure for agricultural purposes in Italy.

For cattle and buffalo, the estimation of the emission factor starts with the calculation of a *methane emission rate* (g  $CH_4/m^3/day$ ), obtained from an equation presented by Husted, and which is different for slurry (Husted, 1994) and solid manure (Husted, 1993). The methane emission rate has been transformed to g/m<sup>3</sup>/month. Equations used are presented below (CRPA, 1997[a]): For slurry:

 $CH_4 (g/m^3/day) = e^{(0.68+0.12*average regional monthly temperature)}$ 

For solid manure:

$$CH_4 \; (g/m^3/day) = e^{(-2,3+0,1*\;monthly\;storage\;temperature)}$$

The monthly storage temperature from the solid manure is estimated according to the following equation (Husted, 1994):

T solid manure storage =  $6,7086e^{0,1014t}$  (°C) (average regional monthly temperature )

For temperatures below 10°C emissions are considered negligible.

The volume of slurry and solid manure produced per livestock category has been calculated  $(m^3/head)$  with the average production of slurry and solid manure per livestock category per day  $(m^3/head/day)$  and the days of storage of slurry and solid manure; these days are related to the temporal application dynamics of slurry and solid manure under Italian conditions (CRPA, 1997[a]).

Emission factors for slurry and solid manure (g CH<sub>4</sub>/head/month) are obtained with methane emission rates and the volume of slurry and solid manure produced. Only for slurry a correction factor is applied, because it considers the characteristic of slurry volatile solids content in Italy. Emission factors obtained at this level are calculated for each month; therefore the annual emission factor for each livestock category will be the sum of slurry and solid manure emission factor for all months (kg CH<sub>4</sub>/head/year).

# Method 2: National basis

Methane emission factors for manure management, on a national basis, have also been calculated for slurry and solid manure; different cattle and buffalo categories as well as values of slurry and solid manure production and volatile solid content have been considered (see Table 6.8).

The implied emission factors for dairy cattle, non-dairy cattle and buffalo are the average of the different category emission factors weighted with the livestock.

In 2003, emission factors presented for dairy cattle and non-dairy cattle are 20.05 kg CH<sub>4</sub>/head/year and 10.62 kg CH<sub>4</sub>/head/year, respectively. Emission factor from non-dairy cattle includes: calf, cattle, female cattle and other dairy cattle. IPCC default emissions factors for cool temperature are 14 kg CH<sub>4</sub>/head/year and 6 kg CH<sub>4</sub>/head/year, respectively.

Livestock category	Slurry (kg CH₄/head/yr)	Manure (kg CH4/head/year)	CH₄ manure management for cattle (kg CH₄/head/year)
Calf (vitellini)	4.761	0	4.761
Cattle (bovini)	5.386	3.146	8.531
Female cattle (bovine)	5.512	4.786	10.299
Dairy cattle (vacche da latte)	11.973	8.084	20.057
Female buffalo (bufale)	9.511	9.289	18.800
Other buffalo (bufalini)	3.465	3.001	6.465
Other dairy cattle (altre vacche)	11.464	9.952	21.416

#### Table 6.8 Methane manure management emission factors for cattle and buffalo in 2003

For buffalo, an average emission factor that includes two categories presented by ISTAT, female dairy buffalo (*bufale*) and other buffalo, which includes young buffalo (*altri bufalini*), has been estimated. Emission factors for female buffalo and other buffalo according to Italian characteristics have been 18.8 kg CH<sub>4</sub>/head/year and 8.7 kg CH<sub>4</sub>/head/year, respectively. In 2003, implied emission factor for buffalo has been 14.95 kg CH<sub>4</sub>/head/year, as reported in the CRF, which represents a weighted average between female dairy buffalo and other buffalo. Emission factor for female dairy buffalo (18.8 kg CH<sub>4</sub>/head/year) is close to the value estimated for dairy cattle (20.06 kg CH<sub>4</sub>head/year); emissions per head for both categories (dairy cattle and female dairy buffalo) are higher as compared with other livestock categories.

#### Methane emissions (swine)

For the estimation of swine methane emissions a country-specific methane emission rate has been determined experimentally at the Research Centre on Animal Production (CRPA, 1996). The estimation of the emission factor considers the structure of the storage for slurry (tank and lagoons), type of breeding and seasonal production of biogas. Different parameters have been considered: livestock, average weight for fattening swine and sows, methane emission rate which has been determined experimentally and a reduction of emissions by 8% for covered storage structures. Methane emission rates used are 41 normal litre  $CH_4/100$  kg live weight/day for fattening swine and 47 normal litre  $CH_4/100$  kg live weight/day for sows including piglets (CRPA, 1997[a]). In Table 6.9 country-specific characteristics from swine breeding are presented as well as emission factors used.

In 2003, emission factor for sows including piglets is equal to 20.75 kg CH<sub>4</sub>head/yr and for other swine is equal to 8.22 kg CH<sub>4</sub>/head/yr. Implied emission factor (IEF) from the CRF is equal to 7.76 kg CH<sub>4</sub>/head/year because it refers to the total number of swine including piglets.

The fundamental characteristics of Italian swine production is the high live weight of the animals slaughtered as related to age; the optimum weight for slaughtering to obtain meat suitable for producing the typical cured meats is between 155 and 170 kg of live weight. Such a high live weight must be reached in no less than nine months of age. Additionally, other two specific characteristics have to be considered: feeding in order to obtain high quality meat and the concentration of Italian pig production, which is limited to a small area (Lombardia, Emilia-Romagna, Piemonte and Veneto), representing 75% of national swine resources. All this peculiarities of Italian swine production influenced methane emission factors for manure management as well as nitrogen excretion factors used for estimating nitrous oxide emissions (Mordenti et al., 1997; CRPA, 2000).

Livestock category	Average weight (kg)	Breed live weight (t)	Methane emission rate (nl CH4/100 kg live weight)	Emission factor (kg CH₄/head/yr)
Other swine	83	557.850	14.965	8.22
20-50 kg	35	63.665		
50-80 kg	65	103.025		
80-110 kg	95	143.355		
110 kg and more	135	243.405		
Boar	200	4.400		
Sow	160	134.130	17.155	20.75
Piglets	10	16.370		
Sow	160	117.760		

#### Table 6.9 Methane manure management parameters and emission factors for swine in 2003

Methane emission factors used for calculating other livestock categories from manure management are those proposed by IPCC; according to the yearly average temperature in Italy (13 °C), emission factors chosen belong to the "cold" climatic region (IPCC, 1997).

#### Nitrous oxide emissions

Nitrous oxide emissions have been estimated by using equation 4.18 from IPCC in the Good Practice Guidance (IPCC, 2000). For estimations, different parameters have been used such as number of livestock species, country-specific nitrogen excretion rates per livestock category (CRPA, 2000), fraction of total annual excretion per livestock category related to a manure management system, and emission factors for manure management systems (IPCC, 1997).

Annual nitrogen excretion rates have been estimated by livestock categories and are defined by the livestock population characteristics in Italy on the basis of recent European literature (Smith and Frost, 2000; Smith et al., 2000; Jongbloed et al., 1999) as described by the Research Centre on Animal Production (CRPA, 2000). The fraction of total annual excretion for each livestock category and manure management system has been estimated by CRPA (CRPA, 1997[b]; CRPA, 2000).

Liquid system, solid storage and other management systems (chicken-dung drying process system) have been considered according to their significance and major application in Italy; emission factors used are 0.001 kg N<sub>2</sub>O-N/kg N excreted, 0.02 kg N<sub>2</sub>O-N/kg N excreted and 0.005 kg N<sub>2</sub>O-N/kg N excreted, respectively (IPCC, 1997; IPCC, 2000). When estimating emissions from manure management, the amount relating to manure excreted while grazing is subtracted and reported in "Agricultural soils" under soil emissions - animal production (see Table 6.10).

Livestock category	Average weight (kg)	N excretedHousing (Ricoveri) (kg/head/yr)	N excreted Grazing (Pascolo) (kg/head/yr)	TOTAL Nitrogen excreted (kg/head/yr)
Non-dairy cattle	387.0	42.6	2.2	44.8
Buffalo	517.6	73.0	7.9	80.9
Dairy cattle	650.0	98.0	10.6	108.6
Other swine	82.8	12.7	0	12.7
Sow (include piglets)	160.0	25.9	0	25.9
Sheep	46.0	1.6	14.6	16.2
Goat	42.4	1.6	14.6	16.2
Horses, mules and asses	528.4	20.0	30.0	50.0
Poultry	1.8	1	0	0.6
Rabbit	1.6	0.6	0	0.6

Table 6.10 Average weight and nitrogen excretions from the different livestock categories in 2003

#### 6.3.3. Uncertainty and time-series consistency

Uncertainty of methane and nitrous oxide emissions from manure management is estimated equal to 102% for annual emissions, as a combination of 20% and 100% for activity data and emissions factor, respectively.

In 2003, livestock methane emissions from manure management were 5.1% (181.94 Gg CH<sub>4</sub>) lower than in 1990 (191.70 Gg CH<sub>4</sub>). From 1990 to 2003, dairy and non-dairy cattle livestock has decreased by 28% and 7%, respectively, whereas swine increased by 8.4%.

Therefore, manure management emissions are driven down mainly because of the reduction in number of cattle, taking into account that cattle contribution to manure management methane emissions are 48.5% while swine contributes for 38.8% in 2003.

In Table 6.11, methane emissions from manure management are presented.

Year	Dairy cattle	Non-dairy cattle	Buffalo	Sheep	Goat	Horse	Other equines	Poultry	Swine	Rabbit	TOTAL
1990	52.957	52.591	1.273	1.901	0.183	0.426	0.071	13.822	67.293	1.187	191.704

Table 6.11 Trend in CH<sub>4</sub> emissions due to manure management, 1990-2003 (Gg)

In 2003, nitrous oxide emissions from manure management were 3.6% (12.81Gg N<sub>2</sub>O) higher than in 1990 (12.35 Gg N<sub>2</sub>O). Major contribution to total nitrous oxide emissions are given by the solid storage category with 89.9%, followed by "other" with 6.9% and 3.2% from liquid systems. It has been assumed that chicken-dung drying process system ("other" emissions) has been widely used from 1995 (CRPA, 1997[b], CRPA, 2000). In Table 6.12 nitrous oxide emissions from manure management for the different manure management systems are presented.

Year	Liquid system	Solid storage	Other	TOTAL
1990	0.454	11.898	0.000	12.351
1991	0.459	12.227	0.000	12.685

Table 6.12 Trend in N<sub>2</sub>O emissions due to manure management, 1990-2003 (Gg)

# 6.3.4. Source-specific QA/QC and verification

Specific activities from the MeditAIRanean project for the agriculture sector are mainly focused on the assessment of critical points and uncertainties, evaluation of basic activity data and emission factors. The project is considering specific peculiarities of the European Mediterranean Region taking into account parameters for the calculation of emissions such as climate, technologies, industrial management livestock breeding, etc. Some of the peculiarities related with Italian swine production have already been described in section 6.3.2.

The work is still in progress and results will be used in future submissions.

# 6.3.5. Source-specific recalculations

No specific recalculation has been carried out with exception of the updating of some basic data for 2001 and 2002.

# 6.3.6. Source-specific planned improvements

In the framework of MeditAIRanean project, further inputs are expected for the next submission.

# 6.4. Rice cultivation (4C)

# 6.4.1. Source category description

Methane emissions from rice cultivation are a level key source assessed with the Tier 2 approach. For rice cultivation only methane emissions are estimated, other greenhouse gases do not occur and

nitrous oxide from fertilisation during cultivation is estimated and reported in "Agricultural soils" under direct soil emissions - synthetic fertilizers.

In 2003, methane emissions from rice cultivation were 74.36 Gg, which represents 9.6% of emissions for the agriculture sector (8.6% in 1990) and 4.5% for total methane emissions (4.0% in 1990).

According to specific characteristics of rice cultivation in Italy, methane emissions from rice cultivation are estimated only for an irrigated regime, other categories suggested by IPCC (rainfed, deep water and "other") are not present.

# 6.4.2. Methodological issues

Methane emissions from rice cultivation have been calculated following IPCC Good Practise Guidance, equation 4.42 (IPCC, 2000); adjusted seasonally integrated emission factor and annual harvested area cultivated under specific conditions have been used. Cultivated surface data have been collected from the National Institute of Statistics.

For estimating the seasonally integrated emission factor, a specific study on Italian paddies was carried out in 2000 (Tani, 2000); therefore country-specific characteristics of rice cultivation have been used.

In Italy rice cropping occurs exclusively in flat fields with one harvest per year. Therefore harvested surfaces coincide with cropped and harvested surfaces, differing from tropical countries where more than one harvest per year is possible. Moreover the particularly expensive crop establishment excludes the possibility of non harvested cropped fields.

Field water regime is man managed, following the theoretical continuously flooded agronomic technique, which involves overflowing of rice paddies with 15-25 centimetres of water usually from April-May to August.

For the period of the field submersion, the following assumptions are made: two or three water drainage periods, lasting from 2 to 4 days each, occur in 85% of rice paddies; a clearly uninterrupted submersion in 13-14%; about one month delayed submersion in 1-2%. In the Po valley (except for the Milan rice paddies area) drainage periods are usually short, scarce or non existent. In the Milan area, but mainly in the South of Italy and in the islands where water is scarce, more than three drainage periods per year may occur, sometimes longer than 4 days (Russo and Nardi, 1996; Spanu and Pruneddu, 1996).

Mineral fertilisation is always used and, seldom, manure. Usually fertilisers are surface applied, without deep incorporation. Organic fertilisers used are litters, commercial products and manure. Rice straws are often burned in the field, otherwise reincorporated into the soil (50% in both cases has been assumed); when buried, little quantities of nitrogen are also added. The above-mentioned applications are usually used in two or three periods, the first of which always before sowing, that is on dry soil, and the others during the growing season.

On the basis of the information reported above, in Italy estimations of methane emissions consider rice cultivation with an irrigated regime, which includes continuous flooded, intermittently flooded-single aeration and intermittently flooded-multiple aeration regimes.

Seasonally integrated emission factor has been adjusted with the following parameters: seasonally integrated emission factor for continuously flooded fields without organic fertilisers (33g  $CH_4/m^2$ ·year), scaling factor to account for the differences in ecosystem and water management regime (range 0.5-1), scaling factor which varies for both types and amount of amendment applied (1.5), and the scaling factor for soil type (IPCC default =1). The seasonally integrated emission factor used (33 g  $CH_4/m^2$ .year) has been increased by 20% taking into account post harvest emissions; therefore it becomes 39.6 g  $CH_4/m^2$ ·year (Wassmann et al., 1994). In Table 6.13, all parameters used for the estimation of methane emissions from rice cultivation are presented.

Rice cultivation v	water regimes	Scaling factor to account for the differences in ecosystem and water management regime	Scaling factor for organic amendment	Seasonally integrated emission factor (g CH <sub>4</sub> /m <sup>2</sup> .year)	Adjusted seasonally integrated emission factor (g CH <sub>4</sub> /m <sup>2</sup> .year)
Continuous flooded		1	1.5	39.6	59.40
T	Single aeration	0.75	1.5	39.6	44.55
Intermittently flooded	Multiple aeration	0.5	1.5	39.6	29.70

Table 6.13. Parameters used for estimating methane emissions from rice cultivation

A coefficient equal to 0.5 has been attributed to "Irrigated, intermittently flooded - multiple aeration", which was considered as representative even the short and modest drainage periods in the Po valley or longer periods in the South of Italy. For "Irrigated, intermittently flooded - single aeration" a value of 0.75 was attributed in consideration that one month or more delayed field submersions are responsible for about 25% of emission reduction with respect to continuous floods. This value has been deduced from Schütz results, assuming that the flooding delay generates a proportional reduction of the emissions (Schütz et al., 1989 [a]).

Assuming that the area involved in rice straw and other organic matter amendments is about 50% of the total, the scaling factor of 2 has been applied, thus the final average increment factor is 1.5 (Schütz et al.,1989 [a], Yagi and Minami, 1990).

Field measurements of methane emission rates were performed in rice paddies of the Italian Rice Research Institute (*Istituto Sperimentale per la Cerealicoltura, Sezione Specializzata per la Risicoltura*). During the experiments diurnal variation as well seasonal variation of methane emissions rates were verified. Average seasonal methane emission rates from unfertilised rice paddies are based in more than 600 individual measurements of methane emission rates (per vegetation period) obtained from 1983-1986, and vary between 0.16 and 0.38 g CH<sub>4</sub>/m<sup>2</sup>day, with a mean value of 0.28 g CH<sub>4</sub>/m<sup>2</sup>day. Lowest values were obtained in 1985, when the average CH<sub>4</sub> emission rate did not exceed 0.16 g CH<sub>4</sub>/m<sup>2</sup>day. Additionally, diurnal and seasonal variations were positively correlated with soil temperature at 1 to 15-cm depth, indicating that the process leading to methane emissions from rice cultivation is equal to 33 g/m<sup>2</sup> CH<sub>4</sub>, yr and is derived from research studies (Schütz et al., 1989 [a], [b]).

# 6.4.3. Uncertainty and time-series consistency

Uncertainty of emissions from rice cultivation has been estimated equal to 40% as a combination of 3% and 40% for activity data and emissions factor, respectively.

In 2003, methane emissions from rice cultivation were 1.5% (74.364 Gg CH<sub>4</sub>) higher than in 1990 (73.264 Gg CH<sub>4</sub>). The main driving force for methane emissions is the harvested area from rice cultivation, which has increased by 1.5%, from 215,442 ha/year in 1990 to 218,675 ha/year in 2003. Higher values of methane emissions are present in 1994 (80.24 Gg), 1995 (81.36 Gg) and 1996 (80.78 Gg) and are also related to an increase in harvested area of 235,951 ha/year, 239,259 ha/year and 237,551 ha/year, respectively.

In Table 6.14, methane emissions from rice cultivation and harvested area are presented.

	Harvested area (10 <sup>9</sup> m <sup>2</sup> /yr)	Methane emissions (Gg)
1990	2.154	73.26
1991	2.063	70.17
1992	2.164	73.58
1993	2.317	78.81
1994	2.360	80.24
1995	2.393	81.36
1996	2.376	80.78
1997	2.328	79.18
1998	2.227	75.73
1999	2.208	75.08
2000	2.203	74.93
2001	2.176	74.01
2002	2.187	74.36
2003	2.187	74.36

#### Table 6.14 Harvested area and methane emissions from rice cultivation, 1990-2003 (Gg)

Lack of experimental data and of knowledge about the occurrence and duration of drainage periods in Italy is the major cause of uncertainty. The assumption of the same water regime surfaces assessment for all previous years introduces another important uncertainty in the results. Further possible improvements in estimates by carrying out provincial estimations on the basis of the relation between emissions and temperature would be limited since the largest Italian rice production is in the Po valley, more than 98% of the total, where monthly temperatures of the rice paddies are similar.

#### 6.4.4. Source-specific QA/QC and verification

This source category is covered by the general QA/QC procedures.

# 6.4.5. Source-specific recalculations

No major recalculations have been carried out.

#### 6.4.6. Source-specific planned improvements

In the framework of MeditAIRanean project, further inputs to refine the estimation are expected for the future submissions.

# 6.5. Agriculture soils (4D)

#### 6.5.1. Source category description

Direct and indirect nitrous oxide emissions from agricultural soils are key sources at level and trend assessment, both with Tier 1 and Tier 2 approaches, while animal production is key source at level and trend assessment with the Tier 2 approach, taking in account the uncertainty. In 2003, nitrous oxide emissions from agricultural soils were 59.50 Gg, which represents 82.3% of emissions for the agriculture sector (83.1% in 1990) and 43.5% for total nitrous oxide emissions (47.3% in 1990). Nitrous oxide emissions from this source mainly consisted of direct soil emissions, 28.29 Gg, and

indirect soil emissions, 25.78 Gg, which represents together the 90.9% of total agricultural soil emissions (90.1% in 1990).

In Italy, agricultural soil emissions are estimated for direct and indirect soils and animal production. For direct soil emissions all sources have been estimated: synthetic fertilizers, animal waste applied to soil, N-fixing crops and cultivation of histosols. For indirect soil emissions, atmospheric deposition and nitrogen leaching and run-off have been estimated. Nitrous oxide emissions from animal production are calculated together with the manure management category on the basis of nitrogen excretion, and reported in agricultural soils.

## 6.5.2. Methodological issues

Methodologies used for estimating nitrous oxide emissions from "Agricultural soils" follow the IPCC approach. Emission factors suggested by IPCC (IPCC, 1997) and by the Research Centre on Animal Production (CRPA, 1997[b]; CRPA, 2000) have been used; activity data have been collected from different sources. A summary of data used and their sources for estimations of nitrous oxide emissions is presented in the following box:

Data used for estimating agricultural soil emissions
--

Data	Reference
Fertilizer distributed (t/yr)	ISTAT, several years [b]
Nitrogen content (%)	ISTAT, several years [b]
N excretion (kg/head/yr)	CRPA, 2000
Cultivated surface (ha/yr)	ISTAT, several years [b], [c], [f]
Annual crop production (t/yr)	ISTAT, several years [b], [c], [f]
N fixed by type of species (kg N/ha)	Erdamn,1959 in Giardini, 1983
Residue/crop product ratio by crop type	CEESTAT, 1992
Crop residue production (t dry matter/ha/yr)	CRPA/CNR, 1992
Dry matter content by crop type	CRPA/CNR, 1992
Protein content in dry matter by crop type	CEESTAT, 1992
Livestock data	ISTAT, several years [b], [c], [g]

For estimating nitrous oxide direct soil emissions, the IPCC approach has been followed, some modifications have been included because of country-specific peculiarities (IPCC, 1997; IPCC, 2000); emissions related to the  $F_{SN}$ ,  $F_{AM}$ ,  $F_{CR}$ ,  $F_{BN}$  and  $F_{OS}$  amounts have been estimated, then N<sub>2</sub>O-N emissions have been calculated on the basis of IPCC emission factors (IPCC, 2000) and converted to N<sub>2</sub>O emissions multiplying by coefficient 44/28; therefore in order to obtain the total direct soil emissions they have been added. Animal production emissions have been estimated according to the methodology described in section 6.3.2, for the manure management. Indirect emissions have been estimated using methodologies suggested by IPCC (IPCC, 1997).

For direct emissions from agricultural soils the following parameters have been estimated:

- Synthetic fertilizers (F<sub>SN</sub>)
- Animal waste applied to soil (F<sub>AM</sub>)
- N-fixing crops (F<sub>BN</sub>)
- Crop residues (F<sub>CR</sub>)
- Cultivation of histosols (F<sub>os</sub>)

The total use of synthetic fertilizer (expressed in t N/year) has been estimated for all years and for each type of fertilizer. Calculation of synthetic fertilizer use ( $F_{SN}$ ) is obtained by multiplying the total use of fertilizer by (1- FRAC<sub>GASF</sub>), where FRAC<sub>GASF</sub> is the fraction of total synthetic fertilizer nitrogen that is emitted as NO<sub>x</sub> +NH<sub>3</sub>. In Italy, FRAC<sub>GASF</sub> has been calculated for all time series on the basis of N-NH<sub>3</sub> and N-NO<sub>x</sub> emission estimations from fertilised soils. Nitrous oxide emissions for synthetic fertilizers were obtained by multiplying  $F_{SN}$  with emission factor 0.0125 kg N-N<sub>2</sub>O/kg N (IPCC, 1997). In Table 6.15, fertilizers distribution, nitrogen content (%) and total use of

fertilizer are presented. In 2003, the total use of synthetic fertilizers has been equal to 824,649 t N, while  $F_{SN}$  has been equal to 745,417 t N.

Type of fertilizers	Fertilizers distributed (t/yr)	Nitrogen content (%)	Total use of synthetic fertilizers (t N/yr)
Ammonium sulphate	127,728	20.8%	26,550
Calcium cianamide	13,895	19.8%	2,751
Ammonium nitrate < 27%	332,377	28.2%	93,689
Ammonium nitrate > 27%	243,564	28.2%	68,654
Calcium nitrate	70,426	15.4%	10,844
Urea + others	881,602	43.5%	383,934
Phosphate nitrogen	469,265	18.1%	85,079
Potassium nitrogen	65,176	15.5%	10,105
NPK nitrogen	867,754	12.5%	108,358
Organic mineral	355,366	9.8%	34,684
TOTAL	3,427,152		824,649

#### Table 6.15 Total use of synthetic fertilizer, t N/yr in 2003

The manure nitrogen used as fertiliser in Italy, corrected for  $NH_3$  and  $NO_x$  emissions and excluding manure produced during grazing (kg N/yr) has been calculated with the IPCC methodology (IPCC, 1997) and country-specific N excretion values suggested by the Research Centre on Animal Production have been considered. Final  $F_{AM}$  (t/yr) value has been estimated by summing all  $F_{AM}$  for each livestock category multiplied by the number of animals and emissions are calculated with the emission factor 0.0125 kg N-N<sub>2</sub>O/kgN (IPCC, 1997). In Table 6.16 N excreted by livestock category and  $F_{AM}$  values are presented. In 2003 the  $F_{AM}$  has been equal to 394,878 t N.

	TOTAL N excreted (t N/yr)	F <sub>AM</sub> (t N/yr)
Non-dairy cattle	211,850	125,040
Buffalo	18,596	10,662
Dairy cattle	206,481	116,388
ther swine	85,383	49,639
ow	19,055	10,864
heep	128,822	4,340

ther (rabbit)	11,091	6,318
OTAL	825,472	394,878

Table 6.16. Total N excretion by livestock category and  $F_{\text{AM}}$  in 2003

Nitrogen input from N-fixing crops ( $F_{BN}$ , kg N/year) has been calculated with a country-specific methodology according to peculiarities in Italy, which considers not only N-fixing crops but also legumes forage.  $F_{BN}$  has been calculated with two parameters: cultivated surface and nitrogen fixed per hectare (Erdamn 1959 in Giardini, 1983). Emissions are finally multiplied by the emission factor 0.0125 kg N\_N2O/kgN (IPCC, 1997). In Table 6.17, N-fixing species cultivated in Italy are presented. In 2003,  $F_{BN}$  has been equal to 175,133 t N.

	Cultivated surface (ha)	Nitrogen fixed (kg N/ha/yr)	TOTAL N fixed (t N/yr )
Bean, fresh seed (fagiolo)	23,720	40	949
Bean, dry seed (fagiolo)	9,180	40	367
Broad bean, fresh seed (fava)	9,736	40	389
Broad bean, dry seed (fava)	44,098	40	1,764
Pea, fresh seed (pisello)	11,478	50	574
Pea, dry seed (pisello)	9,771	72	704
Chickpea (cece)	5,694	40	228
Lentil (lenticchia)	1,745	40	70
Tare (veccia)	6,500	80	520
Lupin ( <i>lupino</i> )	3,000	40	120
soya bean (soia)	152,052	58	8,819
Alfalfa (erba medica)	767,678	194	148,930
Clover grass (trifoglio)	113,594	103	11,700
TOTAL	1,158,246		175,133

#### Table 6.17. Parameters used for estimating N-fixed from crops (2003)

For the estimation of nitrogen input from crop residues ( $F_{CR}$ ), also a country-specific methodology has been used according to national characteristics. The total amount of crop residues has been estimated (t dry matter/year) for all crops, and the following parameters have been used: annual crop production (t/year), residue/crop product ratio, and dry matter content by type of crop (%); when using cultivated surface (ha) activity data, only the crop residue production (t dry matter/ha/year) parameter has been used for estimating the total amount of crop residues.

The nitrogen content from cereals, legumes, tubers and roots and legumes forages crop residues (t N/year) has been estimated by multiplying the total amount of crop residue by the reincorporated fraction (1- FRAC<sub>BURN</sub>, where FRAC<sub>BURN</sub> is the fraction of crop residue that is burned rather than left on field equal to 0.1 kg N/kg crop-N), and the nitrogen content in dry matter by type of crop. The nitrogen content has been obtained dividing the protein content in dry matter by 6.25. F<sub>CR</sub> is obtained by adding the nitrogen content from all crop residues. In 2003, F<sub>CR</sub> has been equal to 119,273 t N. Emissions are obtained by multiplying the nitrogen content from crop residues with the emission factor 0.0125 kg N-N<sub>2</sub>O/kg N (IPCC, 1997).

In Italy, the area of organic soils cultivated annually (histosols) is estimated to be 9,000 hectares (CRPA, 1997[b]); this value is then multiplied by 8 kg N-N<sub>2</sub>O/hectare/year as suggested by the Good Practice Guidance (IPCC, 2000). The data for surface area, reproduced in the national soil map of the year 1961, have been supplied by the Experimental Institute for the study and protection of soil from Florence (ISSDS). These values have been verified with related data for Emilia Romagna region, where this type of soil is most prevalent.

As mentioned in section 6.3.2, when estimating nitrous oxide emissions from manure management, the amount relating to manure excreted while grazing is subtracted and reported in "Agricultural

soils" under animal production. In Table 6.10, N excreted - housing (kg/head/year) used for estimations are presented. Final nitrous oxide emissions are estimated with the total N excreted from grazing (include all livestock categories), the number of animals, and the emission factor 0.02 kg N<sub>2</sub>O-N/kg N excreted (IPCC, 1997).

For indirect emissions from agricultural soils the following parameters have been estimated:

- Atmospheric deposition
- Nitrogen leaching and run-off

The estimation of nitrous oxide emissions due to atmospheric deposition of NH<sub>3</sub> and NO<sub>x</sub> has followed IPCC approach (IPCC, 1997). Parameters which have been used are: total use of synthetic fertilizer, t N/year (see Table 6.15), FRAC<sub>GASF</sub> emission factor; total N excreted by livestock (kg/head/year), FRAC<sub>GASM</sub> emission factor and emission factor 0.01 kg N<sub>2</sub>O-N per kg NH<sub>3</sub>-N + NO<sub>x</sub>-N emitted (IPCC, 1997; IPCC, 2000). FRAC<sub>GASM</sub> has been calculated for all time series and livestock categories because national N excreted values are available (CRPA, 2000).

The estimation of nitrous oxide emissions due nitrogen leaching and run-off has also followed IPCC approach (IPCC, 1997). Parameters which have been used are: total use of synthetic fertilizer, t N/yr (see Table 6.15), total N excreted by livestock (kg/head/year), FRAC<sub>LEACH</sub> emission factor 0.3 N/kg nitrogen of fertiliser or manure and the emission factor 0.025 Kg N<sub>2</sub>O-N per kg nitrogen leaching/run-off (IPCC, 1997; IPCC, 2000).

### 6.5.3. Uncertainty and time-series consistency

Uncertainty for nitrous oxide emissions from agricultural soils (direct soil emissions, indirect soil emissions and animal production) is equal to 102%, as combination of 20% and 100% for activity data and emission factor, respectively. In 2003, nitrous oxide emissions from agricultural soils were 2.2% (59.50 Gg N<sub>2</sub>O) lower than in 1990 (60.86 Gg N<sub>2</sub>O). Major contributions come from direct soil emissions (28.29 Gg) and indirect soil emissions (25.78 Gg), with 47.6% and 43.3%, respectively. In a detailed analysis, N<sub>2</sub>O from nitrogen leaching and run-off has the highest contribution with respect to total agricultural soil emissions with 19.45 Gg N<sub>2</sub>O in 2003 (32.7%); also emissions from synthetic fertilizers have a high contribution with respect to total N<sub>2</sub>O emissions are mainly related to the nitrogen content in fertilizers and animal wastes; therefore, emissions are mainly related to the use of fertilizers in the country as well as the variation in livestock number (see Table 6.18).

Year	Direct Soil Emissions	Animal Production	Indirect Soil emissions	TOTAL	
1990	29.43	6.02	25.41	60.86	
1991	30.79	5.93	26.68	63.40	
1992	31.26	5.96	27.00	64.22	
1993	31.65	6.06	27.75	65.46	
1994	30.16	6.76	27.14	64.06	
1995	28.86	6.94	26.54	62.34	
1996	28.27	7.11	26.09	61.47	
1997	30.20	7.06	27.48	64.73	
1998	28.98	7.06	26.56	62.60

2002	28.98	5.62	26.22	60.82	
2003	28.29	5.42	25.78	59.50	

Table 6.18. Nitrous oxide emission trends from Agricultural soils, 1990-2003 (Gg)

# 6.5.4. Source-specific QA/QC and verification

Synthetic fertilisers and their nitrogen content have been compared with the international FAO agriculture database statistics (FAO, 2005). In Table 6.19, national and FAO time series of total N applied are reported. Differences between national data and FAO database are related to the difference in data elaboration (ISTAT, 2004). Differences could be attributed to different factors. First, national data are more disaggregated by substance than FAO data and the national N content is considered for each substance, see Table 6.15, while FAO utilises default values. Besides, differences could also derive from different products classification.

Year	National data	FAO database
1990	757 509	857 000
1991	837 402	906 000
1992	884 121	909 000
1993	945 290	918 000
1994	875 536	882 000
1995	797 500	875 000
1996	756 057	876 000
1997	856 945	855 000
1998	774 707	845 000
1999	791 982	868 000
2000	785 594	828 000
2001	808 963	773 161
2002	819 352	785 314
2003	824 649	Not available

#### Table 6.19 Total annual N in fertiliser applied from 1990 to 2003 (tonnes)

#### 6.5.5. Source-specific recalculations

No major recalculations have been done for the agricultural soils category; activity data for last years have been updated.

#### 6.5.6. Source-specific planned improvements

In the framework of MeditAIRanean project, further inputs are expected for the next submission.

#### 6.6. Field burning of agriculture residues (4F)

#### 6.6.1. Source category description

Methane and nitrous oxide emissions from field burning agriculture residues are not key sources. In 2003, methane emissions from this source were 0.54 Gg, which only represents 0.1% of emissions for the agriculture sector (0.07% in 1990); nitrous oxide emissions were 0.01 Gg, which represents 0.02% of emissions for the agriculture.

#### 6.6.2. Methodological issues

Emissions from field burning of agriculture residues have been calculated with a country-specific methodology. IPCC suggestions for parameter calculation have been considered (amount of residues produce, the amount of dry residues, the total biomass burned, and the total carbon and nitrogen released). Activity data used for estimating burning of agriculture residues have been summarised in the following box.

Data	Reference
Annual crop production	ISTAT, several years [b]; [f]
Removable residues/product ratio	CEESTAT, 1992
Fixed residues/removable residues ratio	ENEA, 1994
Fraction of dry matter in residues	CEESTAT, 1992; Borgioli, 1981; CRPA/CNR, 1992; IPCC, 1997
Fraction of the field where "fixed" residues are burned	CEESTAT, 1992; IPCC, 1997; ANPA-ONR, 2001
Fraction of residues oxidized during burning	IPCC, 1997
Fraction of carbon from the dry matter of residues	IPCC, 1997
Raw protein content from residues (dry matter fraction)	CEESTAT, 1992; Borgioli, 1981
IPCC Default Emission rates (CH <sub>4</sub> , N <sub>2</sub> 0)	IPCC, 1997

Data used for estimating field burning of agriculture residues emission (2003)

Emissions from burning of agriculture residues, both fixed and removable, have been estimated with the same methodology but reported in two different sectors; emissions from fixed residues, stubble (*stoppie*), burnt on open fields are reported in this category (4F) while emissions from removable residues (*asportabili*) burnt off-site are reported under the 6C category, waste incineration, in the waste sector.

In the following, the methodology for estimating emissions is described; it refers to fixed residues burnt but the same steps are followed to calculate emissions from removable residues burnt reported in the waste sector.

The methodology for estimating methane emissions has considered different parameters:

- a) Amount of "fixed" burnable residues<sup>6</sup> (t), calculated with the annual crop production, the removable residues/product ratio, and the "fixed" residue/removable residues ratio.
- b) Amount of dry residues in the "fixed" residue<sup>7</sup> (t dry matter), calculated with the amount of burnable residues and the fraction of dry matter.
- c) Amount of "fixed" dry residues oxidized<sup>8</sup> (t dry matter), calculated with the amount of dry residues in the "fixed" residues, fraction of the field where "fixed" residues are burned, and the fraction of residues oxidized during burning.
- d) Amount of carbon from stubble burning release in air<sup>9</sup> (t C), calculated with the amount of "fixed" dry residue oxidized and the fraction of carbon from the dry matter of residues.
- e) C-CH<sub>4</sub> from stubble burning<sup>10</sup> (t C-CH<sub>4</sub>), calculated with the amount of carbon from stubble burning release in air and the default emissions rate for C-CH<sub>4</sub>, equal to 0.005 (IPCC, 1997).

In 2003, final methane emissions from on field burning of agriculture residues ( $0.54 \text{ Gg CH}_4$ ) are estimated by multiplying the C-CH<sub>4</sub> value ( $0.4043 \text{ Gg C-CH}_4$ ) with the coefficient 16/12. In Table 6.20 parameters used for the estimation of methane emissions from on field burning of agriculture residues are presented.

For estimating nitrous oxide emissions, the same amount of "fixed" dry residue oxidized described above has been used; further parameters are:

- a) Amount of nitrogen from stubble burning release in air<sup>11</sup> (t N), calculated with the amount of "fixed" dry residue oxidized and the fraction of nitrogen from the dry matter of residues. The fraction of nitrogen has been calculated considering raw protein content from residues (dry matter fraction) divided by 6.25.
- b) N-N<sub>2</sub>O from stubble burning<sup>12</sup> (t N-N<sub>2</sub>O), calculated with the amount of nitrogen from stubble burning release in air and the default emissions rate for N- N<sub>2</sub>O, equal to 0.007 (IPCC, 1997).

<sup>&</sup>lt;sup>6</sup> Quantità di residuo "fisso" bruciabile (produzione totale) (ton)

<sup>&</sup>lt;sup>7</sup> Quantità di residuo secco nel residuo "fisso" (ton di sostanza secca)

<sup>&</sup>lt;sup>8</sup> Quantità residuo secco "fisso" ossidato (ton di sost. secca)

<sup>&</sup>lt;sup>9</sup> Quantità di carbonio rilasciato in aria dalla combustione delle stoppie (tonnellate di carbonio)

<sup>&</sup>lt;sup>10</sup> Emissione di C-CH4 dalla combustione delle stoppie (tonnellate di C-CH4)

<sup>&</sup>lt;sup>11</sup> Quantità di azoto rilasciato in aria dalla combustione delle stoppie (ton di azoto)

<sup>&</sup>lt;sup>12</sup> Emissione di N-N2O dalla combustione delle stoppie (tonnellate di N-N2O)

In 2003, final nitrous oxide emissions from on field burning of agriculture residues (0.012 Gg  $N_2O$ ) are estimated by multiplying the N-N<sub>2</sub>O value (0.0074 Gg N) with the coefficient 44/28. In Table 6.21 parameters used for the estimation of methane emissions from field burning of agriculture residues are presented.

Сгор	Harvested annual production (t*1000)	Amount of "fixed" burnable residues (t*1000)		Amount of "fixed" dry residues oxidized (t *1000 dry matter)	Amount of carbon from stubble burning (t*1000 C)	C-CH <sub>4</sub> from stubble burning (t C-CH <sub>4</sub> )

Table 6.21 Parameters used for the estimation of nitrous oxide from agriculture residues (2003)

#### 6.6.3. Uncertainty and time-series consistency

Uncertainty for methane and nitrous oxide emissions from field burning of agriculture residues are estimated to be 54% as a result of 50% and 20% for activity data and emission factor, respectively. In 2003, methane emissions from field burning of agriculture residues were 13.5% (0.54 Gg CH<sub>4</sub>) lower than in 1990 (0.62 Gg CH<sub>4</sub>). Nitrous oxide emissions were 0.01 Gg N<sub>2</sub>O, as mentioned before, and are the same for all time series (see Table 6.22). Variation in time series is related to cereal production by crops.

Year	<b>Methane</b> emissions	Nitrous oxide emissions		
1990	0.62	0.013		
1991	0.68	0.014		
1992	0.66	0.014		
1993	0.64	0.013		
1994	0.64	0.013		
1995	0.62	0.013

2002	0.60	0.013		
2003	0.54	0.012		

Table 6.22 Methane and nitrous oxide emission trends from field burning of agriculture residues, between 1990 and 2003 (Gg)

# Chapter 7: LAND USE, LAND USE CHANGE AND FORESTRY [CRF SECTOR 5]

# 7.1 Overview of sector

 $CO_2$  emissions and removals occur as a result of changes in land-use and from forests. The sector is responsible for 81.9 Mt of  $CO_2$  removals from the atmosphere in 2003.

The 2003 IPCC Good Practice Guidance for LULUCF have been entirely applied for all the categories of this sector as detailed data were available from national statistics and from researches at national and regional level, whereas for category 5A (Forest Land) estimates were supplied by a growth model, applied to national forestry inventory data, with country specific used emission factors.

 $CO_2$  emissions from forest fires have been included in the calculation of the net carbon stocks reported in 5A.

Greenhouse gas removals and emissions in the main categories of the LULUCF sector in 2003 are shown in Figure 7.1:

Figure 7.1 Greenhouse gas removals and emissions in LUCF sector in 2003 [Gg CO<sub>2</sub> eq.]

In Table 7.1 emission and removal time series is reported.

 Table 7.1 Trend in greenhouse gas emissions from the LULUCF sector 1990-2003

For the land use conversion, land use change matrices have been used; the matrices have permit to point out the average areas of transition land, separately for each initial and final land use (i.e. forest land, grassland, etc.).

In the following Table 7.2, the land use matrices are reported, while the methodological issues relating to the different land uses are given in the respective category paragraphs.

 Table 7.2 Land use change matrices for the years 1990-2003

Recalculations of emissions and removals have been carried out on the basis of the new IPCC Good Practice Guidance for LULUCF (IPCC, 2003). Strong deviations from the precedent sectoral estimates occurred, due to the severe changes in the methodology.

Further identification of critical issues and uncertainties in the estimations derived from the participation at workshops and pilot projects (MATT, 2002). Specifically, the European pilot project to harmonise the estimation and reporting of EU member states, in 2003, led to a comparison among national approaches and problems related to the estimation methodology and basic data needed (JRC, 2004).

Quality control activities have been undertaken in order to assure completeness and consistency in the time series and correctness in the sum of sub-categories; where possible, activity data comparison among different sources (FAO database<sup>13</sup>, ISTAT data<sup>14</sup>) have been made. Data entries have been checked several times during the compilation of the inventory; particular attention has been focussed on the categories showing significant changes between two years in succession.

# 7.2 Forest Land (5A)

### 7.2.1 Source category description

Under this category,  $CO_2$  emissions, from living biomass, dead organic matter and soils, from forest land remaining forest land and from land converted in forest land have been reported.

Net carbon stocks change by land converted in forest land, for the living biomass, dead organic matter and soils sectors, is included in the assessment of carbon stocks change in living biomass, dead organic matter and soils for forest land remaining forest land.

Forest land removals share 68% of total CO<sub>2</sub> LULUCF emissions and removals, in particular the living biomass removals represent 45%, while the removals from dead organic matter and soils stand for 7% and 48% of total forest land CO<sub>2</sub> removals, respectively.

# 7.2.2 Methodological issues

#### Forest Land remaining Forest Land

All the data concerning the growing stock and the related carbon are assessed by a model (Federici et al., 2005), estimating the evolution in time of the Italian forest carbon pools, according to the GPG classification and definition: living biomass, both aboveground and belowground, dead organic matter, including dead wood and litter, and soils as soil organic matter.

Model input data for the forest area, per region and inventory typologies<sup>15</sup>, were the First Italian National Forest Inventory (IFN) data and the Second Italian National Forest Inventory data.

The Italian Ministry of Agriculture and Forests (MAF) and the Experimental Institute for Forest Management (ISAFA) carried out the first National Forest Inventory in 1985. As a result of the first IFN based on a regular sampling grid of 3 km by 3 km, the global Italian extent of forest resources was about 8.7 million hectares (MAF/ISAFA, 1988). A second national forest inventory, using a grid of 1 km by 1 km, had been launched in 2001. Preliminary results of the first inventory phase, consisting in interpretation of orthophotos, were used as input data for the model. This source of information refers to the 2002 (MAF/ISAFA, 2004).

<sup>&</sup>lt;sup>13</sup> FAO, 2005. FAOSTAT, http://faostat.fao.org

<sup>&</sup>lt;sup>14</sup> ISTAT, several years [a], [b], [c]

<sup>&</sup>lt;sup>15</sup>The inventory typologies are classified in 4 main categories: Stands, Coppices, Plantations and Protective Forests. The typologies for each category are:

Stands: norway spruce, silver fir, larches, mountain pines, mediterranean pines, other conifers, european beech, turkey oak, other oaks, other broadleaves.

Coppices: european beech, sweet chestnut, hornbeams, other oaks, turkey oak, evergreen oaks, other broadleaves, conifers.

Plantations: *eucalyptuses coppices, other broadleaves coppices, poplar stands, other broadleaves stands, conifers stands, others*. Protective Forests: *rupicolous forest, riparian forests, shrublands* 

The estimation for 1990 was calculated through a linear interpolation between the 1985 and 2002 data. By assuming that the defined trend may well represent the near future, it was possible to extrapolate data for 2003.

Additional source of information is the National Statistics Institute (ISTAT), which provides annual data on forest area extent. Unfortunately the forest definition adopted by ISTAT implies a minimum cover density of 50% and a minimum forest extent of 0.5 hectares. This leads to an underestimation of the actual forest resources, as less dense formations are not considered. This is the reason why such an important set of historical data was not used to estimate and forecast the forest area extent for the requested years.

To estimate the growing stock of Italian forest, from 1990 to 2003, the following methodology was applied:

- 1. the initial growing stock volume is the 1985 growing stock data (MAF/ISAFA, 1988)
- 2. starting from 1985, for each year, the current increment per hectare [m<sup>3</sup> ha-<sup>1</sup>] is computed with the derivative Richards function<sup>16</sup>, for each forest typology by the Italian yield tables collection.
- 3. starting from 1986, for each year the growing stock per hectare [m<sup>3</sup> ha<sup>-1</sup>] is computed, from the previous year growing stock volume, with the addition of the calculated increment ("y" value of the derivative Richards) for the current year and subtraction of the losses due to harvest, mortality and fire for the current year.

The relationship can be summarized as follows:

$$v_{i} = \frac{V_{i-1} + I_{i} - H_{i} - F_{i} - M_{i} - D_{i}}{A_{i}}$$

where:

 $I_i = f(v_{i-1}) \cdot A_{i-1}$ 

in which the current increment is estimated year by year applying the derived Richards function and

$$\frac{dy}{dt} = \frac{k}{v} \cdot y \cdot \left[ 1 - \left(\frac{y}{a}\right)^{v} \right] + y_{0}$$

(first derivative)

where the general constrain for the parameters are the following:

$$a_k > 0$$
  $-1 \le v \le \infty e \quad v \ne 0$ 

<sup>&</sup>lt;sup>16</sup> In the followed approach the Richards function is fitted through the data of growing stock  $[m^3]$  and increment  $[m^3 y^{-1}]$  obtained by the data of the national forestry inventory and yield tables collection. The independent variable, x, represents the growing stock of the stand, while the dependent variable y is the correspondent increment computed with the Richards function - first derivative.

The constant  $y_0$  is derived from the data of age and volume reported in the yield tables: more precisely  $y_0$  has the value of the volume for the age 1. After choosing the function, it is fitted to the measurements by non-linear regression. The minimization of the deviation is performed by the least squares method. The model performances were evaluated against the data by validation statistics according to Jabssen and Heuberger (1995).

- $v_i$  is the volume per hectare of growing stock for the current year
- $V_{i-1}$  is the total previous year growing stock volume
- $I_i$  is the total current increment of growing stock for the current year
- $H_i$  is the total amount of harvested growing stock for the current year
- $F_i$  is the total amount of burned growing stock for the current year
- Mi is the annual rate of mortality
- D is the annual rate of drain and grazing for the protective forest
- A<sub>i</sub> is the total area referred to a specific forest typology for the current year
- $v_{i-1}$  is the previous year growing stock volume per hectare
- $A_{i\text{-}1}\ \ \, \text{is the total area referred to a specific forest typology for the previous year}$
- f is the Richards function reported above

The average rate of mortality, the fraction of standing biomass per year, used for the calculation was 0.0116, concerning the evergreen forest, and 0.00117, for deciduous forest, according to the GPG (IPCC, 2003).

The rate of draining and grazing, applied to the protective forest, has been estimated as 3%.

The total commercial harvested wood, for construction and energy purposes, has been obtained from national statistics (ISTAT, several years [a]) even if data on biomass removed in commercial harvest published by ISTAT are probably underestimated, particularly concerning fuelwood consumption (Ciccarese et al., 1999). Data of wood use for construction and energy purposes, reported in m<sup>3</sup>, are disaggregated at NUT2 level, in sectoral statistics (ISTAT, several years [a]) or at NUT1 level for coppices and high forests, in the national statistics (ISTAT, several years [c]). These figures have been subtracted, as losses, to the growing stock volume, as abovementioned.

Carbon amount released by forest fires was included in the overall assessment of the carbon stocks change. The amount of burned growing stock related to the burned area has been derived by the growing stock of the specific forest typology, weighted with the fraction having, as numerator, the specific typology surface and, as denominator, the total surface of the category (i.e. *stands, coppices, plantations, protective forests*). The assessed growing stock has, finally, been subtracted to the total growing stock, as aforesaid, considering all the computed biomass oxidised.

In the following, the default value of carbon fraction of dry matter (0.5 t d.m.) has been applied to obtain carbon amount from biomass.

Once estimated the growing stock, the amount of aboveground tree biomass (dry matter) belowground biomass (dry matter) and dead mass (dry matter), from 1990 to 2003, can be assessed.

With regard to the aboveground biomass:

1. starting from the 1985 growing stock data, reported in the IFN, the amount of aboveground tree biomass [t dry matter] was calculated, for each forest typology, with the relation:

Aboveground tree biomass(d.m.) =  $GS \cdot BEF \cdot WBD \cdot A$ 

where:

GS = volume of growing stock (MATT/ISAFA, 1988) [m<sup>3</sup>]

BEF = Biomass Expansion Factors for the conversions of volume to aboveground tree biomass (ISAFA, 2004)

WBD = Wood Basic Density  $[t d.m. m^{-3}]$ 

A = total area referred to a specific forest typology (MATT/ISAFA, 1988)

The BEF were derived for each forest typology and wood basic density values were different for the main tree species.

- 2. starting from 1985, for each year, the current increment per hectare [m<sup>3</sup> ha-<sup>1</sup>] is computed with the derivative Richards function, for each forest typology by the Italian yield tables collection.
- 3. starting from 1986, for each year the growing stock per hectare [m<sup>3</sup> ha<sup>-1</sup>] is computed, from the previous year growing stock volume, with the addition of the calculated increment ("y" value of the derivative Richards) for the current year and subtraction of the losses due to harvest, mortality and fire for the current year, as described above. Re-applying the relation:

Aboveground tree biomass =  $GS \cdot BEF \cdot WBD \cdot A$ 

it is possible to obtain the aboveground tree biomass [t dry matter] for each forest typology, for each year, starting from the 1986.

In the following Table 7.3 biomass expansion factors for the conversions of volume to aboveground tree biomass and wood basic densities are reported:

	International describes	BEF	Wood Basic Density
	Inventory typology	aboveground biomass / growing stock	Dry weigth t/ fresh volume

<b>Table 7.3 Biomass Expansion</b>	<b>Factors and Woo</b>	d Basic Densities
------------------------------------	------------------------	-------------------

Using the preliminary results of the *RiselvItalia Project* carried out by ISAFA (ISAFA, 2004), belowground biomass was estimated applying a BEF to the growing stock. The belowground biomass is computed, as:

Belowground biomass(d.m.) =  $GS \cdot BEF \cdot WBD \cdot A$ 

where:

GS = volume of growing stock [m<sup>3</sup>] BEF = Biomass Expansion Factors for the conversions of volume to belowground biomass WBD = Wood Basic Density [t d.m. m<sup>-3</sup>]

A = total area referred to a specific forest typology

Also in this case, the BEFs and WBDs were derived for each forest typology:

	The state of the late	BEF	Wood Basic Density
	Inventory typology	belowground biomass / growing stock	Dry weigth t/ fresh volume
	norway spruce	0.29	0.38
	silver fir	0.28	0.38

Table 7.4 Biomass Expansion Factors and Wood Basic Densities

The net carbon stock change of living biomass has been calculated according to the GPG for LULUCF (IPCC, 2003), from the aboveground tree biomass and belowground biomass:

 $\Delta C_{\text{Living biomass}} = \Delta C_{\text{Above ground biomass}} + \Delta C_{\text{Below ground biomass}}$ 

where the total amount of carbon has been obtained from the biomass (d.m.), multiplying by the conversion factor carbon content / dry matter.

The deadwood biomass was estimated applying a dead mass expansion factor (DEF<sup>17</sup>) of 20%, as the only available national information refers to dead standing trees in high forest stands. The dead mass [t dry matter] is:

Dead mass (d.m.) =  $GS \cdot BEF \cdot WBD \cdot DEF \cdot A$ 

<sup>&</sup>lt;sup>17</sup> In accordance with the FAO –GFRA Update 2005 Specification of National Reporting Tables for FRA 2005 (FAO, 2004 [a])

where:  $GS = volume of growing stock [m^3]$  BEF = Biomass Expansion Factors for the conversions of volume to aboveground tree biomass $<math>WBD = Wood Basic Density [t d.m. m^3]$  DEF = Dead mass expansion factorA = total area referred to a specific forest typology

The total litter carbon amount is estimated from the aboveground carbon amount with linear relations, deduced from national CONECOFOR Programme data (Corpo Forestale, 2005; Cutini, 2002), per forestry use, stands (resinous, broadleaves, mixed stands) and coppices. In Table 7.5 the different relations used to obtain litter carbon amount per ha [t C ha<sup>-1</sup>] from the aboveground carbon amount per ha [t C ha<sup>-1</sup>] have been reported:

	Inventory typology	Relation litter – aboveground C per ha
	norway spruce	$y = 0.0145 \cdot x + 1.4798$

Table 7.5 Relations litter - aboveground carbon per ha

The dead organic matter carbon pool is defined, in the GPG, as the sum of the dead wood and the litter.

 $\Delta C_{\text{Dead Organic Matter}} = \Delta C_{\text{dead mass}} + \Delta C_{\text{litter}}$ 

The total amount of carbon for dead organic matter has been obtained from the dead organic matter (d.m.), multiplying by the conversion factor carbon content / dry matter.

The total soil carbon amount is estimated from the aboveground carbon amount, with linear relations, deduced from national CONECOFOR Programme data (Corpo Forestale, 2005; Cutini, 2002), per forestry use – stands (resinous, broadleaves, mixed stands) and coppices. In Table 7.6 the different relations used to obtain soil carbon amount per ha [t C ha<sup>-1</sup>] from the aboveground carbon amount per ha [t C ha<sup>-1</sup>] have been reported:

	Inventory typology	Relation soil – aboveground C per ha
	norway spruce	$y = 0.4041 \cdot x + 57.874$

#### Table 7.6 Relations soil - aboveground carbon per ha

#### Land converted in Forest Land

The area of land converted to forest land is always coming from grassland. There is no occurrence for other conversion. Carbon stocks change due to grassland converting to forest land is included in table 5.A.1 of the CRF, i.e. forest land remaining forest land.

 $CO_2$  emissions due to wildfires in forest land remaining forest land are included in table 5.A.1, carbon stocks change in living biomass, decrease.

#### 7.2.3 Uncertainty and time-series consistency

Estimates of removals by forest land are based on application of the above-described model. To assess the overall uncertainty related to the year 1990–2003, the Tier 1 Approach has been followed. The uncertainty linked to the year 1985 has been computed (the first National Forest Inventory was carried out in 1985) with the relation:

$$E_{1985} = \frac{\sqrt{\left(E_{AG_{1985}} \cdot V_{AB_{1985}}\right)^2 + \left(E_{BG_{1985}} \cdot V_{BG_{1985}}\right)^2 + \left(E_{D_{1985}} \cdot V_{D_{1985}}\right)^2 + \left(E_{L_{1985}} \cdot V_{L_{1985}}\right)^2 + \left(E_{S_{1985}} \cdot V_{S_{1985}}\right)^2 + \left(E_{S_{1$$

where the terms  $V_{AG_{1985}}$ ,  $V_{BG_{1985}}$ ,  $V_{D_{1985}}$ ,  $V_{L_{1985}}$  e  $V_{S_{1985}}$  stand for the 1985 carbon stocks of the five pools, aboveground, belowground, dead mass, litter and soil, while, with the letter E, the related uncertainties have been indicated. In the table 7.7 the relations for assessing the overall uncertainties associated to the carbon pools have been reported:

Carbon pool	Relation for uncertainty assessing
Aboveground	$E_{AB_{1985}} = \sqrt{E_{NFI}^{2} + E_{BEF_{1}}^{2} + E_{BD}^{2} + E_{CF}^{2}}$
Belowground	$E_{BG_{1985}} = \sqrt{E_{NFI}^2 + E_{BEF_2}^2 + E_{BD}^2 + E_{CF}^2}$
Dead mass	$E_{D_{1985}} = \sqrt{E_{AG_{1985}}^2 + E_{DEF_{1985}}^2}^2$
Litter	$E_{L_{1985}} = \sqrt{E_{LS_{1985}}^2 + E_{LR_5}^2}^2$
Soil	$E_{S_{1985}} = \sqrt{E_{SS_{1985}}^2 + E_{SR_5}^2}$

Table 7.7 Relations for assessing uncertainties of the C pools

where the term  $E_{NFI}$  stands for the uncertainty associated to the growing stock data given by the first National Forest Inventory,  $E_{BEF_1}$  points to uncertainty related to biomass expansion factors for the aboveground biomass,  $E_{BD}$  is the basic density uncertainty and the term  $E_{CF}$ indicates the conversion factor uncertainty, where GPG default values have been used (IPCC, 2003). In the relation for the belowground carbon pool, the term  $E_{BEF_2}$  stands for the uncertainty related to the expansion factor used in the assessing of belowground biomass from growing stock data; GPG default value have been used (IPCC, 2003). Concerning the dead mass relation,  $E_{DEF}$  is the uncertainty of dead mass expansion factor, from the GPG (IPCC, 2003), while  $E_{LS_{1985}}$  and  $E_{SS_{1985}}$  are the uncertainties related to the litter and soil carbon stock data deduced from the CONECOFOR Programme (Corpo Forestale, 2005). Finally the terms  $E_{LR_{1985}}$  and  $E_{SR_{1985}}$  are defined as the uncertainties related to linear regressions used to assessing the litter and soil carbon stocks. In Table 7.8, the values of carbon stocks in the five pools, for the 1985, and the abovementioned uncertainties are reported:

$\begin{array}{c ccccc} Aboveground biomass & V_{AG} & 128.3 \\ \hline & Aboveground biomass & V_{BG} & 29.6 \\ \hline & Belowground biomass & V_D & 19.4 \\ \hline & Dead mass & V_D & 19.4 \\ \hline & Litter & V_L & 14.5 \\ \hline & Soil & V_S & 205.6 \\ \hline & Growing stock & E_{NFI} & 3.2\% \\ \hline & BEF_1 & E_{BEF1} & 30\% \\ \hline & BEF_2 & E_{BEF2} & 30\% \\ \hline & BEF_2 & E_{BEF2} & 30\% \\ \hline \end{array}$

Table 7.8 Carbon stocks and uncertainties for the year 1985

The uncertainties related to the carbon pools and the overall uncertainty for 1985 has been computed and shown in Table 7.9, using the relations in Table 7.7.

Aboveground biomass	E <sub>AG</sub>	42.59%
Belowground biomass	E <sub>BG</sub>	42.59%
Dead mass	$E_D$	52.10%
Litter	$E_{\rm L}$	45.09%
Soil	$E_{S}$	152.05%
<b>Overall uncertainty</b>	E <sub>1985</sub>	88.49%

Table 7.9 Uncertainties for the year 1985

The overall uncertainty related to the 1985 (the year of the first National Forest Inventory) has been propagated through the years, till 2003, following Tier 1 approach. The equation for the estimates of the 1986 overall uncertainty is shown:

$$E_{1986} = \frac{\sqrt{\left(E_{AG_{1986}} \cdot V_{AB_{1986}}\right)^2 + \left(E_{BG_{1986}} \cdot V_{BG_{1986}}\right)^2 + \left(E_{D_{1986}} \cdot V_{D_{1986}}\right)^2 + \left(E_{L_{1986}} \cdot V_{L_{1986}}\right)^2 + \left(E_{S_{1986}} \cdot V_{S_{1986}}\right)^2}{\left|V_{AB_{1986}} + V_{BG_{1986}} + V_{D_{1986}} + V_{L_{1986}} + V_{S_{1986}}\right|^2}$$

The abovementioned relation is similar to the equation for 1985 uncertainty, apart from the terms linked to aboveground biomass: the biomass increment has been computed with the methodology described in 7.2.2. Methodological issues with reference to the forest land remaining forest land. Therefore the equation for the estimate of the aboveground biomass uncertainty is:

$$E_{AG_{1986}} = \sqrt{\left(\frac{\sqrt{\left(E_{NFI} \cdot V_{NFI}\right)^{2} + \left(E_{I} \cdot V_{I}\right)^{2} + \left(E_{H} \cdot V_{H}\right)^{2} + \left(E_{F} \cdot V_{F}\right)^{2} + \left(E_{D} \cdot V_{D}\right)^{2} + \left(E_{M} \cdot V_{M}\right)^{2}}{\left|V_{NFI} + V_{I} + \left(-V_{H}\right) + \left(-V_{F}\right) + \left(-V_{D}\right) + \left(-V_{MOR}\right)}\right|^{2}}\right)^{2} + E_{BEF_{1}}^{2} + E_{BD}^{2} + E_{CF}^{2}^{2}$$

Growing stock uncertainty (NFI 1985)	E <sub>NFI</sub>	3.2%	
Current increment (Richards) <sup><math>18</math></sup>	E <sub>NFI</sub>	51.6%	
Harvest <sup>19</sup>	$E_{H}$	30%	
Fire <sup>20</sup>	$E_{\rm F}$	30%	
Drain and grazing	E <sub>D</sub>	30%	
Mortality	$E_{M}$	30%	
$BEF_1$	E <sub>BEF1</sub>	30%	
$BEF_2$	E <sub>BEF2</sub>	30%	
DEF	E <sub>DEF</sub>	30%	
<i>Litter (stock + regression)</i>	$E_L$	45%	
Soil (stock + regression)	$E_{S}$	152%	
Basic Density	E <sub>BD</sub>	30%	
C Conversion Factor	E <sub>CF</sub>	2%	

In Table 7.10 the quantities and related uncertainties required from the equation for the estimate of the overall aboveground biomass uncertainty are reported:

#### Table 7.10 Uncertainties for the aboveground biomass for the year 1986

The uncertainties related to the carbon pools and the overall uncertainty for 1986 are shown in Table 7.11:

Aboveground biomass	E <sub>AG</sub>	42.68%
Belowground biomass	$E_{BG}$	42.68%
Dead mass	E <sub>D</sub>	52.17%
Litter	$E_L$	45.09%
Soil	$E_{S}$	152.05%
Overall uncertainty	E <sub>1985</sub>	88.32%

Table 7.11 Uncertainties for the year 1986

Following Tier 1 approach and the abovementioned methodology, the overall uncertainty in the estimates produced by the described model has been quantified; in Table 7.12 the uncertainties of the 1990-2003 period are reported:

<sup>&</sup>lt;sup>18</sup> The current increment is estimated by the derived Richards function (see 7.2.2. Methodological issues - Forest Land remaining Forest Land .; Uncertainty has been assessed considering the standard error of the linear regression between the estimated values and the corresponding current increment values reported in the National Forest Inventory <sup>19</sup> Good Practice Guidance default value (IPCC, 2003)

<sup>&</sup>lt;sup>20</sup> Good Practice Guidance default value (IPCC, 2003)

1985	88.49%
1986	88.32%
1987	91.65%
1988	91.82%
1989	91.69%
1990	91.62%
1991	91.45%
1992	91.21%
1993	91.12%
1994	90.96%
1995	90.70%
1996	90.46%
1997	90.26%
1998	90.12%
1999	89.92%
2000	89.74%
2001	89.54%
2002	89.27%
2003	89.10%

#### Table 7.12 Overall uncertainties 1985 - 2003

The overall uncertainty in the model estimates between 1990 and 2003 has been assessed with the following relation:

$$E_{1990-2003} = \frac{\sqrt{\left(E_{1990} \cdot V_{1990}\right)^2 + \left(E_{2003} \cdot V_{2003}\right)^2}}{\left|V_{1990} + V_{2003}\right|}$$

where the terms V stands for the growing stock  $[m^3 ha^{-1} CO^2 eq]$  while the uncertainties have been indicated with the letter E. The overall uncertainty related to the year 1990–2003 is equal to 63.88%.

The table reporting the uncertainties referring to all the categories (Forest Land, Cropland, Grassland, Wetlands, Settlements, Other Land) is shown in Annex 1.

### 7.2.4 Source-specific planned improvements

The final result of the new forest inventory, available in 2006, will allow a more precise evaluation of the estimated time series, in order to reduce the related uncertainty.

Improvements will be also related to the outcome of European research projects on carbon stock inventories in Europe. Specifically for Italy, two projects are in progress: INFOCARB- Carbon fluxes and Pools in Forest Ecosystems and Progetto Kyoto which should estimate the carbon amount in the Lombardy region. Details of the projects can be found at the website links: http://www.cealp.it, http://www.flanet.org.

Further improvements will be related to the estimate of the emissions/removals due to the area converted in forest land, currently included in the estimate of the forest land remaining forest land.

The fraction of  $CO_2$  emissions due to forest fires, now included in the estimate of the forest land remaining forest land, will be pointed out.

In the next submissions an upgrade of the used model is foreseen to achieve the above cited improvements and to obtain more accurate estimates of the carbon stored in the dead wood, litter and soil pools, using the outcomes of research projects on carbon stocks inventories, with a special focus on the Italian territory.

# 7.3 Cropland (5B)

# 7.3.1 Source category description

Under this category,  $CO_2$  emissions, from living biomass, dead organic matter and soils, from cropland remaining cropland and from land converted in cropland have been reported.

Cropland removals share 16.7% of total  $CO_2$  LULUCF emissions and removals, in particular the living biomass removals represent 95%, while the emissions from soils stand for 5% of total cropland  $CO_2$  emissions and removals.

# 7.3.2 Methodological issues

# Cropland remaining Cropland

Cropland includes all annual and perennial crops; the change in biomass has been estimated only for perennial woody crops, since, for annual crops, increase in biomass stocks in a single year is assumed equal to biomass losses from harvest and mortality in that same year. Therefore activity data for cropland remaining cropland concerns only perennial woody crops.

The estimates of carbon stocks changes are applied to aboveground biomass only, according to the GPG (IPCC, 2003), as there is not sufficient information to estimate carbon stocks change in dead organic matter pools. To assess change in carbon in cropland biomass, the Tier 1 based on highly aggregated area estimates for generic perennial woody crops, has been used; therefore default factors of aboveground biomass carbon stock at harvest, harvest/maturity cycle, biomass accumulation rate, biomass carbon loss, for the temperate climatic region have been applied, even though they are not very representative of the Mediterranean area, where the most common woody crops are crops like olive groves or vineyards that have, for instance, different harvest/maturity cycles.

Furthermore these crops are unlikely totally removed after an amount of time equal to a nominal harvest/maturity cycle (30 years for temperate climate region), as implied by the basic assumption of Tier 1, since the croplands are abandoned or consociated with annual crops. The biomass clearing is relatively unusual. This is the reason why no biomass carbon loss is estimated, since no data about biomass clearing, in wooden cropland, are available.

Net changes in cropland C stocks obtained are equal to 5.741 Tg C for 1990, and 5.699 Tg C for 2003.

In the GPG, carbon stocks for soils are measured to a default depth of 30cm and do not include C in surface residue, i.e. dead organic matter, or changes in inorganic carbon, for Tier1 and Tier2 methods.

Changes in carbon stocks in mineral soils in total cropland have been estimated following changes in management that impact soil carbon content. Previous soil carbon stock  $[SOC_{(0-T)}]$  and soil carbon stock in the inventory year  $[SOC_0]$  for the cropland area have been estimated from the reference carbon stocks. According to the indications of national experts, the carbon content of one hectare of land, at the default depth of 30cm, has been estimated as equal to 44,5  $\pm$  10 t (Ciccarese *et al.*, 2000).

Default stock change factors, factor for land use  $(F_{LU})$ , factor for management  $(F_{MG})$ , and input factor  $(F_I)$ , have been selected among the relative stock change factors for different management activities on cropland, given in GPG, Table 3.3.4 (IPCC, 2003).

In the subsequent table the used stock change factors are shown:

	F <sub>LU</sub>	<b>F</b> <sub>MG</sub>	FI
Cropland	0.82	1.0	1.0

#### Table 7.13 Stock change factors for cropland management

With the stock change factors the soil carbon stock [t C] for the inventory year [SOC<sub>0</sub>] and the previous soil carbon stock  $[SOC_{(0-T)}]$  have been estimated, starting from the soil carbon stock for unit of area [t C ha<sup>-1</sup>]. The inventory time period has been established, as the GPG default, in 20 years. The annual change in carbon stocks in mineral soils has been, at last, assessed as described in the equation 3.3.3 of the GPG (IPCC, 2003).

Net changes in soil C stocks obtained are equal to -0.222 Tg C for 1990, and -0.32 Tg C for 2003.

No  $CO_2$  emissions from organic soils or from application of carbonate containing lime or dolomite to agricultural soils have occurred.

# Land converted to Cropland

In accordance with the GPG methodology, estimates of carbon stock change in living biomass and soils have been provided, since there is not sufficient information to estimate carbon stock change in dead organic matter pool.

 $N_2O$  emissions arising from the conversion of land to cropland have been also estimated, and reported in the Common Reporting Format in Table 5(III) -  $N_2O$  emissions from disturbance associated with land-use conversion to cropland.

The carbon stocks change, for land converted to cropland, is equal to the carbon stocks change due to the removal of biomass from the initial land use plus the carbon stocks from one year of growth in cropland following the conversion.

The Tier 1 has been followed, assuming that the amount of biomass is cleared and some type of cropland system is planted soon thereafter. At Tier 1, carbon stocks in biomass immediately after the conversion are assumed to be zero.

The average area of land undergoing a transition from non cropland, only grassland in Italian case, to cropland, during each year, from 1990 to 2003, has been estimated through the construction of the land use change matrices, one for each year; the matrices allow to point out the average areas of transition land separately for each initial and final land use (i.e. forest land, grassland, etc.). The GPG equation 3.3.8 (IPCC, 2003) has been used to estimate the change in carbon stocks resulting from the land use change.

The carbon stocks change per area for land converted to cropland is assumed, following the Tier1, equal to loss in carbon stocks in biomass immediately before conversion to cropland.

For the Italian territory, only conversion from grassland to cropland has occurred; therefore the default estimates for standing biomass grassland, as dry matter, reported in Table 3.4.2 of GPG (IPCC, 2003) for warm temperate – dry have been used, equal to 1.6 t d.m. ha<sup>-1</sup>. Changes in carbon stocks from one year of cropland growth have been obtained by the default biomass carbon stocks reported in Table 3.3.8, for temperate region. In accordance to national expert judgement, it has been assumed that the final crop type, for the areas of transition land, is annual cropland.

As pointed out in the land use matrices reported above, in Table 7.2, conversion of lands into cropland has taken place only in a few years during the period 1990- 2003. C emissions [Gg C] due to change in carbon stocks in living biomass in land converted to cropland, are reported in Table 7.14:

Year	Conversion Area	$\Delta C$ converted land
Teur	k ha	Gg C
1990	-	-
1991	-	-
1992	-	-
1993	41	53.45
1994	54	70.82
1995	54	70.82
1996	79	102.27
1997	-	-
1998	164	213.74
1999	132	171.67
2000	15	18.97
2001	-	-
2002	-	-
2003	-	-

Table 7.14 Change in carbon stock in living biomass in land converted to cropland

Changes in carbon stocks in mineral soils in land converted to cropland have been estimated following land use changes, resulting in a change of the total soil carbon content. Initial land use soil carbon stock  $[SOC_{(0-T)}]$  and soil carbon stock in the inventory year  $[SOC_0]$  for the cropland area have been estimated from the reference carbon stocks. According to the indications of national experts, the carbon content of one hectare of grassland or cropland, at the default depth of 30cm has been estimated as equal to 44,5 ± 10t (Ciccarese *et al.*, 2000).

As above mentioned, only conversion from grassland to cropland has occurred in the Italian territory; different stock change factors ( $F_{LU}$ ,  $F_{MG}$ ,  $F_I$ ) have been used for the different management activities on grassland, initial land use, and cropland, final land use.

With the stock change factors, the cropland soil carbon stock [t C] for the inventory year [SOC<sub>0</sub>] and the grassland land use soil carbon stock  $[SOC_{(0-T)}]$  have been estimated, starting from the soil carbon stock for unit of area [t C ha<sup>-1</sup>]. The inventory time period has been established, as the GPG default, in 20 years. The annual change in carbon stocks in mineral soils has been, at last, assessed as described in the equation 3.3.3 of the GPG (IPCC, 2003), only for the years where conversion has taken place. C emissions [Gg C] due to change in carbon stocks in soils in land converted to cropland are reported in Table 7.15.

No  $CO_2$  emissions from organic soils or from application of carbonate containing lime or dolomite to agricultural soils have occurred.

#### 7.3.3 Source-specific planned improvements

Improvements will concern the implementation of the estimate of carbon change in cropland biomass at a higher disaggregate level, with the subdivision of the activity data in the main categories of woody cropland (orchards, citrus trees, vineyards, olive groves) and the application of different biomass accumulation rates and harvest/maturity cycles for the various categories.

Further investigation will be made to obtain ancillary information about the final crop types, concerning the areas in transition to cropland, in order to obtain a more precise estimate of the carbon stocks change.

Year	Conversion Area	Carbon stock
Teur	k ha	$Gg C yr^{-1}$
1990	-	-
1991	-	-
1992	-	-
1993	41	-11.9
1994	54	-15.8
1995	54	-15.8
1996	79	-22.8
1997	-	-
1998	164	-47.6
1999	132	-38.2
2000	15	-4.2
2001	-	-
2002	-	-
2003	-	-

 Table 7.15 Change in carbon stock in soil in land converted to cropland

# 7.4 Grassland (5C)

# 7.4.1 Source category description

Under this category,  $CO_2$  emissions, from living biomass, dead organic matter and soils, from grassland remaining grassland and from land converted in grassland have been reported.

Grassland emissions share 13.9% of absolute  $CO_2$  LULUCF emissions and removals, in particular the living biomass emissions represent 4%, while the emissions from soils stand for 96% of total grassland  $CO_2$  emissions.

### 7.4.2 Methodological issues

### Grassland remaining Grassland

Forage crops, permanent pastures, and lands once used for agriculture purposes, but in fact setaside since 1970 has been considered as grasslands.

To assess change in carbon in grassland biomass, the Tier 1 has been used; therefore no change in carbon stocks in the living biomass pool has been assumed, while estimate on carbon stocks changes in soils has been provided. In accordance to the GPG no data regarding the dead organic matter pool have been provided, since not enough information is available.

Changes in carbon stocks in mineral soils in total grassland have been estimated following changes in management that impact soil carbon content. Previous soil carbon stock  $[SOC_{(0-T)}]$  and soil carbon stock in the inventory year  $[SOC_0]$  for the grassland area have been estimated from the reference carbon stocks. According to the indications of national experts, the carbon content of one hectare of land with a soil depth of 30cm can be estimated as equal to 44,5 ± 10t (Ciccarese *et al.*, 2000).

For the two grassland systems (forage crops and permanent pasture, set-aside lands) a set of default stock change factors ( $F_{LU}$ ,  $F_{MG}$ ,  $F_I$ ) has been chosen among the relative stock change factors for grassland management given in GPG, Table 3.4.5 (IPCC, 2003), taking into account the land use, the different level of degradation and the applied input to lands. The land use stock change factor ( $F_{LU}$ ) for the so-called set aside lands has been derived, according to the indications of national experts, from Table 3.4.5 of the GPG (IPCC, 2003).

In the following table the used stock change factors are shown:

Grassland system	$\mathbf{F}_{\mathbf{LU}}$	F <sub>MG</sub>	FI
Forage crops and permanent pasture	1.0	0.95	1.0
Grassland from set aside lands	0.82	1.0	0.92

#### Table 7.16 Stock change factors for grassland management

With the stock change factors the soil carbon stock [t C] for the inventory year [SOC<sub>0</sub>] and the previous soil carbon stock [SOC<sub>(0-T)</sub>] have been estimated, starting from the soil carbon stock for unit of area [t C ha<sup>-1</sup>].

The inventory time period has been established, as the GPG default, in 20 years.

The annual change in carbon stocks in mineral soils has been, at last, assessed as described in the equation 3.4.8 of the GPG. Net changes in soil C stocks obtained are equal to 4.341 Tg C for 1990, and 4.322 Tg C for 2003.

No  $CO_2$  emissions from organic soils or from application of carbonate containing lime have occurred.

# Land converted to Grassland

In accordance with the GPG methodology, estimate of carbon stocks change in living biomass and soils have been provided, since there is not sufficient information to estimate carbon stocks change in dead organic matter pool. Only conversion from cropland to grassland has occurred.

The assessment of emissions and removals of carbon due to conversion of other land uses to grassland requires estimates of the carbon stocks prior to and following conversion and the estimates of land converted during the period over which the conversion has an effect.

As a result of conversion to grassland, it is assumed that the dominant vegetation is removed entirely, after which some type of grass is planted or otherwise established; alternatively grassland can result from the abandonment of the preceding land use, and the area is taken over by grassland. The Tier 1 has been followed, assuming that carbon stocks in biomass immediately after the conversion are equal to 0 t C ha<sup>-1</sup>.

The annual area of land undergoing a transition from non grassland, only cropland in Italian case, to grassland during each year, from 1990 to 2003, has been pointed out, for each initial and final land use, through the use of the land use change matrices, one for each year.

The GPG equation 3.4.13 (IPCC, 2003) has been used to estimate the change in carbon stocks, resulting from the land use change. Concerning Italian territory, only conversion from cropland to grassland has occurred; therefore the default biomass carbon stocks present on land converted to grassland, as dry matter, as supplied by Table 3.4.9 of the GPG for warm temperate – dry, have been used, equal to 6.1 t d.m. ha<sup>-1</sup>. Since, according to national expert judgement, it has been assumed that lands in conversion to grassland are mostly annual crops, carbon stocks in biomass immediately before conversion have been obtained by the default values reported in the Table 3.3.8 of the GPG, for annual cropland.

As pointed out above in the land use matrices, see Table 7.2, the conversion of lands into grassland have taken place only in a few years during the period 1990-2003. C emissions [Gg C] due to change in carbon stocks in living biomass in land converted to grassland, are reported in Table 7.17:

V	Conversion Area	C before	$\Delta C_{growth}$	ΔC	
Year	k ha	t C ha-1 yr-1	t C ha-l	Gg C	
1990	46	5	3.05	-90.2	
1991	24	5	3.05	-47.4	
1992	23	5	3.05	-43.9	
1993	-	5	3.05	-	
1994	-	5	3.05	-	
1995	-	5	3.05	-	
1996	-	5	3.05	-	
1997	25	5	3.05	-48.2	
1998	-	5	3.05	-	
1999	-	5	3.05	-	
2000	-	5	3.05	-	
2001	118	5	3.05	-229.2	
2002	65	5	3.05	-126.2	
2003	98	5	3.05	-191.9	

Table 7.17 Change in carbon stock in living biomass in land converted to grassland

Changes in carbon stocks in mineral soils in land converted to grassland have been estimated following land use changes, resulting in a change of the total soil carbon content. Initial land use soil carbon stock  $[SOC_{(0-T)}]$  and soil carbon stock in the inventory year  $[SOC_0]$  for the grassland have been estimated from the reference carbon stocks. According to the indications of national experts, the carbon content of one hectare of grassland or cropland, at the default depth of 30cm, has been estimated as equal to 44,5 ± 10t (Ciccarese *et al.*, 2000).

As above mentioned, only conversion cropland to grassland has occurred in the Italian territory; different stock change factors ( $F_{LU}$ ,  $F_{MG}$ ,  $F_I$ ) have been used for the for diverse management activities on cropland, initial land us, and grassland, final land use.

With the stock change factors, the grassland soil carbon stock [t C] for the inventory year [SOC<sub>0</sub>] and the cropland land use soil carbon stock [SOC<sub>(0-T)</sub>] have been estimated, starting from the soil carbon stock for unit of area [t C ha<sup>-1</sup>]. The inventory time period has been established, as the GPG default, in 20 years. The annual change in carbon stocks in mineral soils has been, at last, assessed as described in the equation 3.3.3 of the GPG, only for the years where conversion has taken place. C emissions [Gg C] due to change in carbon stocks in soils in land converted to grassland, are reported in Table 7.18:

Year	Conversion Area	Carbon stock
Teur	k ha	$Gg C yr^{-1}$
1990	46	20.1
1991	24	10.6

2002	65	28.2
2003	98	42.8

Table 7.18 Change in carbon stock in soil

# 7.4.3 Source-specific planned improvements

Concerning land in transition to grassland, further investigation will be made to obtain additional information about different types of management activities on grassland, and the crop types, to obtain a more accurate estimate of the carbon stocks change.

# 7.5 Wetlands (5D)

### 7.5.1 Source category description

Under this category, activity data from wetlands remaining wetlands are reported.

## 7.5.2 Methodological issues

Lands covered or saturated by water, all or part of year, which harmonize with the definitions of the Ramsar Convention on Wetlands<sup>21</sup> have been included in this category (MAMB, 1992). No data were available on flooded lands, therefore reservoirs or water bodies regulated by human activities have not been considered. Concerning land converted to wetland, during the period 1990-2003, no land has been in transition to wetlands.

### 7.5.3 Source-specific planned improvements

Improvements will concern the acquirement of data about flooded lands and the implementation of the GPG method to estimate CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>O emissions from flooded lands.

### 7.6. Settlements (5E)

### 7.6.1 Source category description

Under this category, activity data from settlements and from land converted to settlements are reported; CO<sub>2</sub> emissions, from living biomass, from land converted in settlements have been also reported. Settlements emissions share 1.25% of total CO<sub>2</sub> LUCF emissions and removals.

<sup>&</sup>lt;sup>21</sup> Ramsar Convention on Wetlands: <u>http://www.ramsar.org/</u> (Ramsar, 2005)

# 7.6.2 Methodological issues

Up to now there is a lack of data concerning urban tree formations. Therefore it is not possible to give estimates on the carbon stocks changes in living biomass, dead organic matter and soil for this category. Therefore only activity data have been reported. Settlements time series has been developed through a linear interpolation between the 1990 and 2000 data, obtained by the Corine Land Cover<sup>22</sup> maps, relatively to the class "*Artificial surfaces*". By assuming that the defined trend may well be represent the near future, it was possible to extrapolate data for the years 2001-2003.

# Land converted to Settlements

The average area of land undergoing a transition from non-settlements to settlements during each year, from 1990 to 2003, has been estimated with the land use change matrices that have also permitted to specify the initial and final land use. The GPG equation 3.6.1 approach (IPCC, 2003) has been used to estimate the change in carbon stocks, resulting from the land use change. The annual change in carbon stocks, for land converted to settlements, is assumed equal to carbon stocks in living biomass immediately following conversion to settlements, multiplied for the area of land annually converted. The default assumption, for Tier 1, is that carbon stocks in living biomass following conversion are equal to zero.

As reported in the table 7.2, only conversions from grassland and cropland to settlements have occurred in the 1990-2003 period. Concerning grassland converted to settlements, no change in carbon stocks has been computed, as in Tier 1 no change in carbon stocks in the grassland living biomass pool has been assumed. For what concerns cropland in transition to settlements, carbon stocks, for each year and for crops type (annual or perennial), have been estimated, using as default coefficients the factors shown in the following table:

	Biomass carbon stock $t C ha^{-1}$
Annual cropland	5
Perennial woody cropland	63

Table 7.19 Stock change factors for cropland

As indicated in the land use matrices of Table 7.2, the conversion of lands into settlements have taken place only in a few years during the period 1990-2003. In Table 7.20 C emissions [Gg C] due to change in carbon stocks in living biomass in cropland (annual and perennial) converted to settlements are reported:

<sup>&</sup>lt;sup>22</sup> Corine Land Cover, <u>http://www.clc2000.sinanet.apat.it/cartanetclc2000/</u> (APAT, 2004)

	annual crops to	settlements	perennial woody cr	rops to settlements	Total Carbon stock

 Table 7.20 Change in carbon stocks in living biomass in cropland converted to settlements

### 7.6.3 Source-specific planned improvements

Further investigation will be made to obtain additional statistics about settlements, comparing the added information with the time series developed from Corine Land Cover data (APAT, 2004). Urban tree formations will be probed for information, in order to estimate carbon stocks. Moreover improvements will concern acquirement of data sufficient to give estimates of carbon stocks changes in dead organic matter and soils for land in transition to settlements.

# 7.7 Other Land (5F)

Under this category,  $CO_2$  emissions, from living biomass, dead organic matter and soils, from land converted in other land should be accounted for; no data is reported since the conversion to other land is not occurring.

# 7.8 Direct N<sub>2</sub>O emissions from N fertilization (5(I))

 $N_2O$  emissions from N fertilization of cropland and grassland are reported in the agriculture sector; therefore only forest land should be included in this table; no data have been reported, since no fertilizers are applied to forest land.

# 7.9 N<sub>2</sub>O emissions from drainage of soils (5(II))

N<sub>2</sub>O emissions from N drainage of forest or wetlands soils no data have been reported, since no drainage is applied to forest or wetlands soils.

# 7.10 $N_2O$ emissions from disturbance associated with land-use conversion to Cropland (5(III))

# 7.10.1 Source category description

Under this category,  $N_2O$  emissions from disturbance of soils associated with land-use conversion to cropland, according to the GPG (IPCC, 2003).  $N_2O$  emissions from cropland

remaining cropland are included in the agriculture sector of the good practice guidance. The good practice guidance provides methodologies only for mineral soils.

# 7.10.2 Methodological issues

 $N_2O$  emissions from land use conversions are derived from mineralization of soil organic matter resulting from conversion of land to cropland. The average area of land undergoing a transition from non-cropland to cropland during each year, from 1990 to 2003, has been estimated with the land use change matrices; as abovementioned, only conversion from grassland to cropland has occurred in the Italian territory. The GPG equation 3.3.14 has been used to estimate the emissions of N<sub>2</sub>O from mineral soils, resulting from the land use change.

Changes in carbon stocks in mineral soils in land converted to cropland have been estimated following land use changes, resulting in a change of the total soil carbon content. Assuming the GPG default values, 15 and 0.0125 kg N<sub>2</sub>O-N/kg N for the C/N ratio and for calculating N<sub>2</sub>O emissions from N in the soil respectively, N<sub>2</sub>O emissions have been estimated.

In Table 7.21  $N_2O$  emissions resulting from the disturbance associated with land-use conversion to cropland are reported:

V	Conversion Area	Carbon stock	N <sub>net-min</sub>	N <sub>2</sub> O <sub>net-min</sub> -N	N <sub>2</sub> O emissions
Year	k ha	$Gg C yr^{-1}$	kt Nyr-1	kt N <sub>2</sub> O-N yr-1	Gg N <sub>2</sub> 0 yr-1

Table 7.21 N<sub>2</sub>O emissions from land-use conversion to cropland

### 7.11 Carbon emissions from agricultural lime application (5(IV))

Carbon emissions from agricultural lime application are no estimated, since no lime application is occurring.

# 7.12 Biomass Burning (5(V))

### 7.12.1 Source category description

Under this source category,  $CH_4$  and  $N_2O$  emissions from forest fires are estimated, in accordance with the IPCC method.

National statistics on areas affected by fire per region and forestry use, high forest (resinous, broadleaves, resinous and associated broadleaves) and coppice (simple, compound and degraded), were used (ISTAT, several years [a]).

 $CO_2$  emissions due to forest fires in forest land remaining forest land are included in table 5.A.1 of the CRF, under carbon stock change in living biomass - decrease.

# 7.12.2 Methodological issues

In Italy, in consideration of national regulations, forest fires do not result in changes in land use; therefore conversion of forest and grassland does not take place. Anyway  $CO_2$  emissions due to forest fires in forest land remaining forest land are included in table 5.A.1 of the CRF, under carbon stock change in living biomass - decrease. The total biomass reduction due to forest fires, and subsequent emissions, has been estimated following the methodology reported in paragraph 7.2.2.

IPCC method was followed for  $CH_4$  and  $N_2O$  emissions, multiplying the amount of C released from 1990 to 2003, calculated on the basis of regional parameters (Bovio, 1996), by the emission factors suggested in the IPCC guidelines (IPCC, 1997).

# 7.12.3 Source-specific planned improvements

Further investigations will be made to acquire data on grassland fires, in order to provide estimate of  $CO_2$  emissions.

# Chapter 8: WASTE [CRF sector 6]

# 8.1 Overview of sector

The waste sector comprises four source categories:

- 1 solid waste disposal on land (6A);
- 2 wastewater handling (6B);
- 3 waste incineration (6C);
- 4 other waste (6D).

The waste sector share of GHG emissions in the national greenhouse total is presently 2.2% (and was 2.6% in the base year 1990).

The trends in greenhouse gas emissions from the waste sector are summarised in Table 8.1. It clearly shows that methane emissions from solid waste disposal sites (landfills) are by far the largest source category within this sector; in fact these emissions rank among the top-10 key level and key trend sources.

Emissions from waste incineration facilities without energy recovery are reported under category 6C, whereas emissions from waste incineration facilities which produce electricity or heat for energetic purposes are reported under categories 1A2 (Manufacturing industries and construction) and 1A4a (according to the IPCC reporting guidelines).

Under 6D, CH<sub>4</sub> and NMVOC emissions from compost production are reported.

# 8.2 Solid waste disposal on land (6A)

# 8.2.1. Source category description

As mentioned above, methane from landfills is a major key source, both in terms of level and trend. Its share of  $CH_4$  emissions in the national greenhouse total is presently 1.7% (and was 2% in the base year 1990).

The main parameters that influence the estimation of emissions from landfills are, apart of course from the amount of waste disposed into managed landfill, the waste composition, the fraction of methane in the landfill gas and the amount of landfill gas collected and treated, which could influence the emission estimates.

From 2000, municipal solid wastes are disposed only into managed landfills, due to the enforcement of regulations.

The Landfill European Directive (EC, 1999), that has been transposed by the Legislative Decree 13 January 2003 n. 36, will applied definitely to the Italian landfill the next July. Until this deadline, the classification of landfill refers to the old national legislation (Decision 27 July 1984), that is very close to the new one.

The municipal solid wastes are disposed into the 1<sup>st</sup> category landfills, whereas the inert wastes are disposed into the 2<sup>nd</sup> category, type A, landfills; other industrial wastes with different toxicity are disposed into the 2<sup>nd</sup> category, type B and C, and into the 3<sup>rd</sup> category landfills. Methane emissions are expected from 1<sup>st</sup> category landfills, as results from law's disposition, that force only this category having a collecting gas system, due to biodegradability of wastes disposed.

For this reason, only 1<sup>st</sup> category landfills have been considered for the estimation of methane emissions.

For the year 2003, the 1<sup>st</sup> category landfills in Italy are 487, that dispose 21,112 Mt of wastes.

# 8.2.2. Methodological issues

In order to calculate  $CH_4$  emissions from all the landfill sites in Italy, the assumption was made that all the landfills started operation in 1975 and the same parameters have been considered in order to apply the First Order Decay Model (although characteristics of individual sites can vary substantially). Thus, the IPCC Tier 2 methodology has been followed for the emission estimation.

Since CH<sub>4</sub> emissions from landfills are a key source (see above), the present methodology does comply with the IPCC Good Practice Guidance (IPCC, 2000).

Apart from municipal solid waste, sludge from urban wastewater handling plants has also been considered. The share of waste disposed of into uncontrolled landfills, which was 52.7% in 1975, gradually decreases, thanks to the enforcement of new regulations as reported above, and it has been assumed equal to 0 in the year 2000, although emissions are released due to the waste disposed in the past years. The unmanaged sites have been considered 50% deep and 50% shallow.

Parameter values used in the landfill emissions model are:

- 1 total amount of waste disposed;
- 2 fraction of Degradable Organic Carbon (DOC);
- 3 fraction of DOC dissimilated ( $DOC_F$ );
- 4 fraction of methane in landfill gas (F);
- 5 oxidation factor  $(O_X)$ ;
- 6 methane correction factor (MCF);
- 7 methane generation rate constant (k);
- 8 landfill gas recovered (R).

On the basis of data available on waste composition (Ferrari, 1996), the moisture content, the organic carbon content and the fraction of biodegradable organic carbon for each waste stream

(Andreottola and Cossu, 1988), the DOC contents for each waste typology and the methane generation potential values  $(L_0)$  have been generated.

The fraction of DOC dissimilated and the MCF are IPCC default values. The MCF value for unmanaged landfill results as average of the default IPCC values reported for deep and shallow sites.

It is assumed that landfill gas composition is 50% carbon dioxide and 50% methane.

In the following Table 8.2, national parameters are reported; the main difference between national and IPCC DOC values refers to paper and textiles.

	National	National	National	National	National	IPCC
	Waste composition by weight (KgRSUi/100Kg wet RSU)	Moisture Content	Organic Carbon content (KgC/Kg dry RSU)	Fraction of Biodegradable Organic Carbon	DOC (KgC/100Kg wet RSU)	DOC (KgC/100Kg wet RSU)
Food	26.31	60%	0.48	80%	4.04	3.95
Garden and park	4.48	50%	0.48	70%	0.75	1.05
Paper	30.13	8%	0.44	50%	6.10	12.05
Textiles	5.13	10%	0.55	20%	0.51	2.05
Wood and straw	-	20%	0.50	50%		
Σ					11.40	19.10
	IPCC	National	IPCC	IPCC	National	National
	MCF	DOC (KgC/100Kg wet RSU)	DOC <sub>f</sub>	F	L <sub>0</sub> (KgCH <sub>4</sub> /tRSU)	L <sub>0</sub> (m <sup>3</sup> CH <sub>4</sub> /tRSU)
Managed	1	11.40	50%	50%	38.00	51.35
Unmanaged	0.6	11.40	50%	50%	22.80	30.81

Table 8.2 Parameters used to calculate the fraction of DOC and consequently the methane generation potential

On the basis of encouragements of the centralized review of the 2004 GHG inventory Italy's submission, the maximum methane generation rate constant of 0.4 per year has been revised. The new value (k = 0.26) has been calculated making a weighted average of the single k values calculated for each rapidly, moderately and slowly biodegradable fractions, on the basis of their percentage within the waste composition, as reported in Table 8.3. National half life values are suggested by Andreottola and Cossu (Andreottola and Cossu, 1988).

	National	National	IPCC	IPCC
	Half life	Methane generation rate constant	Half life	Methane generation rate constant
Rapidly biodegradable	1 year	0.69	3 year	0.23
Moderately biodegradable	5 years	0.14	14 years	0.05
Slowly biodegradable	15 years	0.05	23 years	0.03
Average	2.66 years	0.26		

 Table 8.3 Half-life values and methane generation rate constant correlated, both national and IPCC values

Concerning NMVOC emissions, it has been assumed that non methane volatile organic compounds are 1.3 weight per cent of methane (Gaudioso et al., 1993): this assumption refers to US EPA data (US EPA, 1990).

# 8.2.3. Uncertainty and time-series consistency

The combined uncertainty in  $CH_4$  emissions from solid waste disposal sites is estimated to be 36.1% in annual emissions, 20% and 30%, respectively, for activity data and emission factors, as suggested by the IPCC Good Practice Guidance (IPCC, 2000).

Due to importance of the sub-sector, the time series of activity data is also reported (Table 8.4), followed by the  $CH_4$  emission trend (Table 8.5).

1990	1995	1996	1997	1998	1999	2000	2001	2002	2003
22,231	25,780	25,960	26,605	26,847	28,364	28,959	29,409	29,864	30,038
91.1%	85.5%	83.3%	80.0%	77.4%	76.7%	75.7%	68.0%	63.1%	59.9%

### 8.2.4. Source-specific QA/QC and verification

A comparison of the national emission factors and parameters used for the estimation with the default IPCC values has been done (see Tables 8.2 and 8.3). The main difference refers to the average degradable organic carbon in the waste and depends on the Italian waste composition.

The values used to calculate the DOC content and the methane generation rate constant have been compared with those reported in a survey by the Hydraulic Department of the University of Rome "La Sapienza" (Muntoni and Polettini, 2002).

A verification on methane recovered time series has been done, on the basis of a new available national survey (Acaia et al., 2004). Concerning CH<sub>4</sub> recovering, figures have been estimated on the basis of data on landfill gas flared available for 1991-1992-1993 (De Poli and Pasqualini, 1997) and data on energy recovered from landfill gas published yearly from 1990 by the Italian Independent System Operator (GRTN, 2003). A recent research (Acaia et al., 2004) for Lombardy Region on landfill gas recovered (both flared and energy use) has been used to verify the average percentage of landfill gas recovered at landfill sites; additionally, data on methane recovered for some disposal sites have been provided by Asja Company, one of the leaders in Italy in the management of landfills, for the years 2001 and 2002 (Asja, 2003).

# 8.2.5. Source-specific recalculations

The methane generation rate constant k that appears in the FOD method is related to the time taken for DOC in waste to decay to half its initial mass (the 'half life' or  $t\frac{1}{2}$ ). The maximum value of k applicable to any single SWDS is determined by a large number of factors associated

with the composition of the waste and the conditions at the site. The most rapid rates are associated with high moisture conditions and rapidly degradable material such as food waste. The slower decay rates are associated with dry site conditions and slowly degradable waste such as wood or paper.

On the basis of encouragements of the centralized review of the 2004 GHG inventory Italy's submission, the maximum methane generation rate constant of 0.4 per year has been revised. The new value (k = 0.26) has been calculated on the basis of the national waste composition and the national 'half-life' values, for the rapidly, moderately and slowly biodegradable matter.

As reported above, sludge from urban wastewater handling plants has also been considered. The whole time series have been revised: sludge disposed in landfill sites has been estimated from the equivalent inhabitants treated in wastewater treatment plants, distinguished in primary and secondary plants (MATT, 1989; ISTAT, 1991; ISTAT, 1993; ISTAT, 1998 [a], [b]), applying the specific per capita sludge production (Masotti, 1996; ANPA, 2001; ApS, 1997); the total amount of sludge per year could be treated by incineration or composting, or once digested could be disposed to soil for agricultural purpose or to landfills (ISTAT, 1998 [a], [b]; De Stefanis et al., 1998).

Other minor modification concerning the oxidation factor has been done, due to an error in the last submission.

A comparison with the previous estimation, in percentage terms, is reported in Table 8.6.

Table 8.6 Differences in percentages between time series reported in the updated time series and 2004 submission

### 8.2.6. Source-specific planned improvements

Improvements are expected due to the entering in force of the landfill directive (EC, 1999). The application of the Directive could implement the availability of data regarding the main parameters influencing the estimation of emission from landfills: the waste composition, the fraction of methane in the landfill gas and the amount of landfill gas collected and treated.

# 8.3 Wastewater handling (6B)

### 8.3.1. Source category description

In Italy wastewater handling is managed mainly using aerobic treatment plants, where the complete-mix activated sludge process is more frequently designed. It is assumed that domestic and commercial wastewaters are treated 100% aerobically, whereas industrial wastewaters are treated 85% aerobically and 15% anaerobically.

Consequently, there are no  $CH_4$  emissions from the treatment of domestic and commercial wastewaters, but only  $N_2O$  emissions from human sewage. Since there are not further  $N_2O$  emissions, they are reported exclusively in human sewage.

CH<sub>4</sub> emissions from sludge generated by Domestic and Commercial Wastewater treatment have been calculated; the stabilization of sludge, both in domestic and industrial wastewater treatment

plants, occurs in aerobic or anaerobic reactors; whereas anaerobic digestion is used, the reactors are of course covered and provided of gas recovery. A percentage from 2 to 5% of domestic and commercial wastewater is treated in Imhoff tanks, where the digestion of sludge occurs anaerobically without gas recovery. Therefore, very few emissions from sludge disposal does occur.

# 8.3.2. Methodological issues

As concerns  $N_2O$  emissions, the default approach suggested by the IPCC Guidelines (IPCC, 1997), and updated in the Good Practice Guidance (IPCC, 2000), based on population and per capita intake protein has been followed. Fraction of nitrogen protein (Frac <sub>NPR</sub>) 0.16 kg N/kg protein and emission factor (EF<sub>6</sub>) default values 0.01 kg N-N<sub>2</sub>O/kg N produced have been used, whereas the value 60 g/capita d of protein intake have been used, as indicate in a survey by the National Research Centre on Nutrition (INRAN, 1997).

The methane estimation concerning industrial wastewaters makes use of the IPCC method based on wastewater output and the respective Degradable Organic Carbon for each major industrial wastewater source. No country specific emission factors of methane per Chemical Oxygen Demand are available so the default value of 0.25 kg CH<sub>4</sub>/kg DC, suggested in the IPCC Good Practice Guidance (IPCC, 2000), has been used for the whole time series.

As recommended by the Good Practice Guidance (IPCC, 2000) for key source categories, data have been collected for several industrial sectors (food and beverage, paper and pulp, organic chemicals, refineries, iron and steel, textile, leather industry). National data have been used in the calculation of the total amount of both COD produced and wastewater output for: refineries (UP, 2004), organic chemicals (FEDERCHIMICA, several years) pulp & paper sector (ANPA-FLORYS, 2001; Assocarta, several years), beer (Assobirra, several years), wine, milk and sugar sectors (ANPA-ONR, 2001 [a]), and leather sector (ANPA-FLORYS, 2000; UNIC, 2003). Production data have been provided by the National Statistic Institute (ISTAT, 2004 [a], [b]).

CH<sub>4</sub> emissions from sludge generated by Domestic and Commercial Wastewater treatment have been calculated using the IPCC default method on the basis of national information on anaerobic sludge treatment system (IPCC, 1997; IPCC 2000).

A recent survey conducted by the National Statistic Institute (ISTAT, 2004 [c]) has provided information on urban wastewater treatment plants in Italy for the year 1999: an investigation on previous references has been done and data on primary treatment plants using Imhoff tanks are also available for 1987 (ISTAT, 1991; ISTAT, 1993) and 1993 (ISTAT, 1998 [a], [b]).

On the basis of the equivalent inhabitants treated in Imhoff tanks, the organic loading 60 g  $BOD_5$ /capita·d, as defined by national legislation and expert estimations (Legislative Decree 11 May 1999, no.152; Masotti, 1996; Metcalf and Eddy, 1991), the fraction of  $BOD_5$  that readily settles equal to 0.3 (ANPA, 2001; Masotti, 1996), and the IPCC emission factor default value of 0.5 g CH<sub>4</sub>/g BOD<sub>5</sub>, CH<sub>4</sub> emissions have been calculated.

# 8.3.3. Uncertainty and time-series consistency

The combined uncertainty in  $CH_4$  emissions from wastewater handling is estimated to be about 104% in annual emissions 100% and 30% respectively for activity data and emission factor uncertainty, coming from the IPCC Good Practice Guidance (IPCC, 2000). The uncertainty in N<sub>2</sub>O emission is 30% both for activity data and emission factor as suggested in the GPG (IPCC, 2000).

The amount of total industrial wastewater production is reported, for each sector, in Table 8.7; as previously noted only the 15% of industrial flows are treated anaerobically.

 $CH_4$  emission trend for industrial wastewater handling for different sectors is shown in Table 8.8, whereas the emission trend for N<sub>2</sub>O emissions both from industrial wastewater handling and human sewage is shown in Table 8.9.

Concerning  $CH_4$  emissions from industrial wastewater, neither wastewater flow nor average COD value change much over time, therefore emissions are stable. The following COD values, expressed in grams per litre for 2003, have been used: 0.1 g/l (Iron and steel); 3.0 g/l (Organic

chemicals); 3.61 g/l (Food and beverages); 0.07 g/l (Pulp and paper); 1.0 g/l (Textile industry); 3.60 g/l (Leather industry). Data on organic load for oil refinery is available only as total annual amount.

### 8.3.4. Source-specific QA/QC and verification

This source category is covered by the general QA/QC procedures. Where information is available, wastewater flows and COD concentrations are checked with those reported yearly by the industrial sectoral reports or technical documentation developed in the framework of the Integrated Pollution and Prevention Control (IPPC) Directive of the European Union (http://eippcb.jrc.es).

### 8.3.5. Source-specific recalculations

Estimation of CH<sub>4</sub> emissions from sludge generated by Domestic and Commercial Wastewater treatment have been implemented this year, on the basis of national information on anaerobic sludge treatment system. As reported above, a recent survey conducted by the National Statistical Institute (ISTAT, 2004 [c]) has provided information on urban wastewater treatment plants in Italy for the year 1999: an investigation on previous references has been done and data on primary treatment plants using Imhoff tanks are also available for 1987 (ISTAT, 1991; ISTAT, 1993) and 1993 (ISTAT, 1998 [a], [b]).

The  $CH_4$  emission trend from sludge generated by Domestic and Commercial Wastewater treatment, together with equivalent inhabitants treated in Imhoff tank and consequently the organic loading per year, is reported in Table 8.10, whereas a comparison with the previous estimation of the total methane for wastewater handling, in percentage terms, is reported in Table 8.11.

Domestic and Commercial Sludge	1990	1995	1996	1997	1998	1999	2000	2001	2002	2003

### 8.3.6. Source-specific planned improvements

No specific activities are planned.

# 8.4 Waste incineration (6C)

### 8.4.1. Source category description

Existing incinerators in Italy are used for the disposal of municipal waste, together with some industrial waste, sanitary waste and sewage sludge for which the incineration plant has been authorized from the competent authority. Other incineration plant are used exclusively for industrial and sanitary waste, both hazardous and not, and for the combustion waste oils, whereas there are few plants that treat residual waste from waste treatments, as well as sewage sludge.

As mentioned above, emissions from waste incineration facilities with energy recovery are reported under categories 1A2 (Manufacturing industries and construction) and 1A4a (Combustion activity, commercial/institutional sector), whereas emissions from other types of waste incineration facilities are reported under category 6C (Waste incineration). For 2003, the 70.5% of the incineration plants, both for the disposal of MSW and for the disposal of other industrial wastes are provided of energy recovering system.

A complete data base of the incineration plants is now available, updated with the information reported in the yearly report on waste production and management published by APAT (APAT-ONR, 2004).

Emissions from removable residues from agricultural production are included in the IPCC category 6C: the total residues amount and carbon content have been estimated by both IPCC and national factors. The detailed methodology is reported in Chapter 6 (6.6.2).

CH<sub>4</sub> emissions from biogenic, plastic and other non-biogenic wastes have been calculated.

# 8.4.2. Methodological issues

As concern GHG emissions from incinerators, the methodology reported in the IPCC Good Practice Guidance (IPCC, 2000) has been used, combined with that reported in the CORINAIR Guidebook (EMEP/CORINAIR, 2001). In fact, a single emission factor for each pollutant has been used combined with plant specific waste activity data.

The emissions have been determined for each type of waste: municipal, industrial, hospital, sewage sludge and waste oils.

A complete data base of these plants has been built, on the basis of various available sources relating to the period of the entire time series, extrapolating data for the years for which there

was no available information (MATT, several years; ANPA-ONR, 1999 [a]; ANPA-ONR, 2001 [b]; APAT-ONR, 2002; APAT-ONR, 2003; APAT-ONR, 2004; APAT, 2002; ANPA-ONR, 1999 [b]; AUSITRA-Assoambiente, 1995; Morselli, 1998; FEDERAMBIENTE, 1998; FEDERAMBIENTE, 2001; AMA-Comune di Roma, 1996; Ambiente, 2001; COOU, 2005).

For each plant a lot of information is reported, among which the year of the construction and possible upgrade, the typology of combustion chamber and gas treatment section, if it is provided of energy recovery (thermal or electric), and of course the type and amount of waste incinerated (municipal, industrial, etc.).

Different procedures were used to estimate emission factors, according to the data available for each type of waste.

Specifically:

- 1 for municipal waste, emission data from a large sample of Italian incinerators were used (these plants represent around 50% in terms of the quantities of waste disposed of annually);
- 2 for industrial waste and waste oil, reference was made to the allowed levels in the authorisation for the management of a group of incinerators taken as a sample;
- 3 for hospital waste, which is usually disposed of alongside municipal waste, the emission factors used for industrial waste were also used;
- 4 for sewage sludge, in absence of specific data, reference was made to the emission limits prescribed by the Guidelines for the authorisation of existing plants issued on the 12<sup>th</sup> July 1990.

With regard to municipal waste, on the basis of the IPCC Guidelines (IPCC, 1997) and referring to the average content analysis on a national scale (FEDERAMBIENTE, 1992), a distinction was made between  $CO_2$  from fossil fuels (generally plastics) and  $CO_2$  from renewable organic sources (paper, wood, other organic materials). Only emissions from fossil fuels, which are equivalent to 35% of the total, were included in the inventory.

On the other hand,  $CO_2$  emissions from the incineration of sewage sludge were not included at all, while all emissions relating to the incineration of hospital and industrial waste were included.  $CH_4$  and  $N_2O$  emissions from agriculture residues removed, collected and burnt 'off-site', as a way to reduce the amount of waste residues, are reported in the waste incineration sub-sector. Removable residues from agriculture production are estimated for each crop type (cereal, green crop, permanent cultivation) taking in account the amount of crop produced, the ratio of removable residue in the crop, dry matter content of removable residue, the ratio of removable residue burned, the fraction of residues oxidised in burning, the carbon and nitrogen content of the residues. Most of these wastes refer especially to the prunes of olives and wine, because of the typical national cultivation. The methodology is the same used to calculate emissions from residues burned on fields, reported in the category 4F, described in details in Chapter 6.

On the basis of carbon and nitrogen content of the residues,  $CH_4$  and  $N_2O$  emissions have been calculated, accounting the first for the 99%, as compared to the whole emissions from waste incineration, and  $N_2O$  emissions for a little bit less.  $CO_2$  emissions have been calculated but not included in the inventory as biomass. All these parameters refer both to the IPCC Guidelines (IPCC, 1997) and country-specific values, when available (CESTAAT, 1992; Borgioli, 1981).

### 8.4.3. Uncertainty and time-series consistency

The combined uncertainty in  $CO_2$  emissions from waste incineration is estimated to be about 25.5% in annual emissions, 5% and 25% concerning respectively activity data and emission factors. As regard N<sub>2</sub>O and CH<sub>4</sub> emissions, the combined uncertainty is estimated to be about 100% and 20.6% in annual emissions.

The emission trend for  $CO_2$  emissions from each type of waste incinerators is shown in Table 8.12 both for plants without energy recovery, reported under 6C, and plants with energy recovery, reported under 1A. In the Table 8.13 N<sub>2</sub>O and CH<sub>4</sub> emissions are summarized. In the period 1990-2003, total emissions increased by 35%; but whereas emissions from plants with

### 8.4.4. Source-specific QA/QC and verification

This source category is covered by the general QA/QC procedures. For those incineration plants reported in EPER register, a verification on emissions has been carried out.

### 8.4.5. Source-specific recalculations

For the year 1998, activity data from those incineration plants which treat MSW have been revised, due to a survey on the Italian incineration plants, published in 2001 (FEDERAMBIENTE, 2001). Activity data have been substitute with those calculated within the data base.

For the year 2002, activity data from those incineration plants which treat industrial waste, that were not available, have been published by APAT and so update.

Methane emissions from biogenic, plastic and other non-biogenic wastes, have been calculated.

Moreover, some mistakes for few plants have been detected relating to the split between with or without energy recovery system.

In Table 8.14 differences with GHG emissions reported last year in percentages are reported. As regard  $CO_2$  and  $N_2O$  emissions reported in 6C category have been diminished while those reported in 1A category increased.

### 8.4.6. Source-specific planned improvements

No specific activities are planned.

# 8.5 Other waste (6D)

### 8.5.1. Source category description

Under this source category  $CH_4$  emissions from compost production have been reported. The amount of waste treated in composting plants has shown a nearly 17-fold increase from 1990 to 2003 (363,519 tons to 6,090,638 tons).

Information on input waste to composting plants are published yearly by APAT since 1996, including data for 1993 and 1994 (ANPA, 1998; ANPA-ONR, 2001 [b]; APAT-ONR, 2002; APAT-ONR, 2003; APAT-ONR, 2004), while for 1987 and 1995 only data on compost production are available (MATT, 1989; AUSITRA-Assoambiente, 1995); on the basis of this information the whole time series has been reconstructed.

### 8.5.2. Methodological issues

The composting plants are classified in two different kinds: the plants that treat a selected waste (food, market, garden waste, sewage sludge and other organic waste, mainly from the agro-food industry); and the mechanical-biological treatment plants, that treat the unselected waste to produce compost, refuse derived fuel (RDF), and in general a selected waste with better characteristics for landfilling or incinerating system.

It is assumed that the 100% of the input waste to the composting plants from selected waste is treated as compost, while in mechanical-biological treatment plants the 30% of the input waste is treated as compost on the basis of national studies and references (Favoino and Cortellini, 2001; Favoino and Girò, 2001).

Since no methodology is provided by the IPCC for these emissions, literature data (Hogg, 2001) has been used for the emission factor, 0.029 g CH4/kg treated waste, equivalent to compost production.

NMVOC emissions have also been estimated: emission factor (51 g NMVOC/kg treated waste) is from international scientific literature too (Finn and Spencer, 1997).

In the Table 8.15 CH<sub>4</sub> and NMVOC emissions are reported.

GAS	1990	1995	1996	1997	1998	1999	2000	2001	2002	2003

## 8.5.3. Uncertainty and time-series consistency

The uncertainty in  $CH_4$  emissions from compost production is estimated to be about 100% in annual emissions, 10% and 100% concerning respectively activity data and emission factors.

# 8.5.4. Source-specific QA/QC and verification

This source category is covered by the general QA/QC procedures.

# 8.5.5. Source-specific recalculations

No recalculation has been done.

## 8.5.6. Source-specific planned improvements

No specific activities are planned.

# **Chapter 9: RECALCULATIONS AND IMPROVEMENTS**

# 9.1 Explanations and justifications for recalculations

To meet the requirements of transparency, consistency, comparability, completeness and accuracy of the inventory, the entire time series from 1990 onwards is checked and revised every year during the annual compilation of the inventory. Measures to guarantee and improve these qualifications are undertaken and recalculations should be considered as a contribution to the overall improvement of the inventory.

Recalculations are elaborated on account of changes in the methodologies used to carry out emission estimates, changes due to different allocation of emissions as compared to previous submissions and changes due to error corrections. Revisions apply to the entire time series.

Specifically this year, in addition to the usual updating of activity data, which can also affect information of previous years, methodological revisions have regarded the inclusion of categories not previously estimated.

The complete revised CRFs from 1990 to 2002 has been submitted as well as the CRF for the year 2003 and recalculation tables have been filled in terms of quantity values for each year. Explanatory information on the major recalculations between the 2004 and 2005 submission are reported in Table 9.1.

The revisions that lead to relevant changes in GHG emissions have been already pointed out in the specific sectoral chapters and summarized in the following section 9.4.1.

# 9.2 Implications for emission levels

The time series reported in the 2004 submission and the series reported this year (2005 submission) by gas and sector are shown in Table 9.2. Specifically, by gas, the comparison and differences in emission levels are reported in Table 9.3.

The most relevant changes affected the last year as well as the whole time series.

Improvements in the calculation of emission estimates have led to a recalculation of the entire time series of the national inventory. Considering the total GHG emissions without  $CO_2$  from LUCF, the emission levels of the base year increased by 0.5% in comparison with the last year submission, whereas emissions for the year 2002 showed an increase by 0.2%.

Detailed explanations of these recalculations are provided in the sectoral chapters. In general, the most relevant changes affected F-gas emissions (from 1996), specifically HFCs, due to the revision of the methodologies and new information available. Other important recalculations concerned  $N_2O$  for the revision of nitric acid production emissions especially for the base year and CH<sub>4</sub> emissions according to the methodological revisions of emission estimates from enteric fermentation in the agriculture sector and from landfills in the waste sector.

5	LUCF	CO2	The considerable differences in the different categories are due to the remarkable dissimilarity beetween the old and the new CRFs. The emissions, estimated according the new classification and definition, have been included in the "Other" category			
δA	Solid Waste Disposal	CH4		Emission factors have been revised on the basis of national information on waste composition and half time of DOC taking in account comments from the expert review		CH4 recovered has been review on the basis of information on energy produced from landfill gas available by the national energy manager
бB	Wastewater Handling	CH4	Emissions for the whole time series have been calculated using the IPCC default method on the basis of national information on anaerobic sludge treatment system			CH4 emissions from sludge producing by Domestic and Commercial Wastewater treatment have been calculated
5C	Waste incineration	CO2		Activity data may have changed in the amount of incinerated wastes treated with/without energy recovering due to new information about the plants		
бC	Waste incineration	CH4	Emissions for the whole time series have been calculated using the IPCC default method			CH4 emissions from incineration plants have been estimated
A	Enteric fermentation	CH4		Emission factor have been revised on the basis of new information	Time series of activity data has been updated	
B1	Fugitive emissions from solid fuels	CH4		Emission factors have been revised following the Good Practice Guidance		CH4 emissions from post minin activities have been estimated
olum	n of the table (see Table lain changes in method	e 8(a)) . ls, emission fa		t column and the name of the categor ulted in recalculation of the estimate o mn.

Table 9.3 Differences in time series between 2005 and 2004 submissions due to recalculations

#### 9.3 Implications for emission trends, including time series consistency

The recalculations, in general, account for an improvement in the overall emission trend and consistency in time series.

In comparison with the time series submitted in 2004, emission levels of the base year, total emissions in  $CO_2$  equivalent without  $CO_2$  emissions from LUCF, increased by 0.5%. Specifically,  $CH_4$  levels have increased by 3% and  $N_2O$  by 4.4%. On the contrary, minor changes affected  $CO_2$  emission levels without LUCF, with a decrease by 0.1%, and F-gases for which the revision has no effect on the base year but accounted for from 1996 onwards.

For the year 2002, changes affected positively  $CO_2$  (+0.5%) as well  $CH_4$  and  $N_2O$  levels (+4.4% and +1.9%, respectively), whereas F-gas levels show a decrease (-49.9% for HFCs and -2.9% for SF<sub>6</sub>).

Due to these recalculations the trend 'base year- year 2002' shows an increase by 8.7% in this year submission, while the increase for the same period was by 9% if considering the previous submission.

Improvements in methodologies used to compile the inventory will guarantee better estimates and minor changes from one year to another for the entire time series.

# 9.4 Recalculations, response to the review process and planned improvements

This chapter summarises the recalculations and improvements made to the Italian GHG inventory since the 2002 inventory was issued in the year 2004.

Besides the inclusion of a new year, the inventory is updated annually by a revision of the existing activity data and emission factors in order to include new information available; the update could also reflect the revision of methodologies. Revisions always applies to the whole time series.

The inventory may also be expanded by including categories not previously estimated if sufficient information on activity data and suitable emission factors have been identified and collected.

# 9.4.1 Recalculations

The key differences that have occurred in emission estimates since the last year submission are reported in Table 9.2 and Table 9.3. A more detailed recalculation for the year 2002 is summarised in Table 9.4

Besides the usual updating of activity data, recalculations may be distinguished in methodological changes, source allocation and error corrections.

All sectors were involved in methodological changes. Specifically:

*Energy*.  $CH_4$  emissions from post mining activities have been estimated.  $CH_4$  emission factors for fugitive emissions, specifically solid fuel, have been revised according to the Good Practice Guidance.

Industrial sector. Most of the relevant recalculations affected the industrial processes sector.

 $CO_2$  and  $N_2O$  emissions from mineral products and chemical industry have been revised and recalculated on account of new information made available by industry. In addition, cross-checks with figures reported in the European Pollutant Emission Register for Italy were carried out.

*Solvent and other product use sector*. N<sub>2</sub>O emissions from the use of this gas for anaesthesia and from aerosol cans have been estimated on the basis of new information made available by industry.

*Agriculture*. CH<sub>4</sub> emission factors for emissions related to enteric fermentation have been revised on the basis of new information.

*LULUCF*. The entire time series has been recalculated using the new methodology proposed in the Good Practice Guidance for LULUCF (IPCC, 2003).

*Waste sector.*  $CH_4$  emissions for waste incinerators have been estimated.  $CH_4$  emissions from landfills have been recalculated on the basis of an in depth analysis of basic parameters used for estimation.

Source allocation was improved in the framework of the implementation of the EU emission trading directive, meetings with the industry sector were held. This results in a better understanding of emissions allocation particularly in the refineries, iron and steel, lime and cement and non ferrous metal sectors.

During the compilation of the inventory for the year 2003 an error in F-gas emissions from fire extinguishers has been detected; specifically the emission factor for HFC-227ea has been corrected for the whole time series.

# 9.4.2 Response to the UNFCCC review process

In 2004 the Italian GHG inventory was subject to the centralized review by the Climate Secretariat on the GHG inventory and NIR submitted in the same year.

In response to the centralized review, recalculation tables for all years have been provided within the submission of the complete set of CRFs 1990-2003. The completeness of the inventory has also improved in the estimation of  $CH_4$  emissions from waste incineration and  $N_2O$  emissions from solvent and other product use. The description of country specific methods and the

rationale behind the choice of emission factors, activity data and other related parameters should have improved the transparency of the present NIR. Particular attention has been paid to check information and values with the relevant references and to the archiving of all the material used for the 2005 submission.

Figures to draw up uncertainty analysis have been checked with the experts and are consistent with the IPCC Good Practice Guidance.

#### 9.4.3 Planned improvements (e.g., institutional arrangements, inventory preparation)

The main priority will concern the establishment of a National System in order to comply with the additional requirements of the Kyoto protocol and the European Monitoring Mechanism. The implementation of the programme is the responsibility of the Ministry for the Environment and Territory, while practical co-ordination is delegated to APAT.

The first actions which are currently being undertaken are the following:

- elaboration of an inventory QA/QC plan which describes specific QC procedures to be implemented during the inventory development process and facilitate the QA procedures including the establishment of quality objectives;
- official designation of a single national entity with the overall responsibility for the national inventory;
- establishment of processes for the official consideration and approval of the inventory, including any recalculations, prior to its submission;
- basic independent review of the inventory before its submission is also under consideration.

Other specific functions are already part of the good practices followed for the inventory preparation.

Sector specific improvements are identified in the relevant chapters.

Generally, improvements will be related to the availability of new and updated information on emission factors, activity data as well as parameters necessary to carry out the estimates. For the energy and industrial sectors, a depth analysis of data from the European Pollutant Emission Register and the Emission Trading scheme will be carried out, i.e for cement and iron and steel. For the LULUCF sector, the Corine Land Cover data will be processed.

Finally, the results of the MeditAIRaneo project will led to a better estimation of  $CH_4$  and  $N_2O$  emissions from the agriculture sector.

There are only few emission values missing, such as potential PFCs, but at the moment no information is available to fill these gaps.

### ANNEX 1: KEY SOURCES AND UNCERTAINTY

#### A1.1 Introduction

The IPCC Good Practice Guidance (IPCC, 2000) recommends as good practice the identification of key source categories in national GHG inventories. A key source category is defined as an emission source that has a significant influence on a country's GHG inventory in terms either of the absolute relative level of emissions or the trend in emissions, or both.

Key source categories therefore are those found in the accumulative 95% of the total annual emissions in the last reported year or belonging to the total trend, when ranked in descending order of magnitude.

The assessment of national key source categories is important because key source categories should receive special consideration in terms of methodological aspects and quality assurance and quality control verification.

Two different approaches are reported in the Good Practice according to whether or not a country has performed an uncertainty analysis of the inventory: the Tier 1 and Tier 2.

When using the Tier 1, key sources categories are identified by means of a pre-determined cumulative emissions threshold, usually fixed at 95% of the total. The threshold is based on an evaluation of several inventories and is aimed at establishing a general level where key source categories should cover up to 90% of inventory uncertainty.

If inventory source-level uncertainties are carried out, the Tier 2 can be used to identify key source categories. The Tier 2 approach is a more detailed analysis that builds on the Tier 1; in fact, the results of the Tier 1 are multiplied by the relative uncertainty of each source category. Key source categories are those that represent 95% of the uncertainty contribution, instead of applying the pre-determined cumulative emissions threshold.

So the factors which make a source a key source are a high contribution to the total, a high contribution to the trend and a high uncertainty.

If both the Tier 1 and Tier 2 are applied it is good practice to use the results of the Tier 2 analysis.

For the Italian inventory, a key source analysis has been carried out according to both the Tier 1 and Tier 2 methods. National emissions have been disaggregated, as far as possible, into the categories proposed in the Good Practice; other categories have been added to reflect specific national circumstances. Both level and trend analysis have been applied.

Summary of the results of the key source analysis is reported in Table 1.3 of chapter 1.

The same categorisation and the same estimates of uncertainty as performed in Table A1. have been used. The table indicates whether a key source arises from the level assessment or the trend assessment.

As far as level emission sources are concerned 23 key sources were individuated accounting for the 95% of the total emission. For the trend, 27 key sources were selected. Jointly for both the level and trend, 29 key sources were totally individuated.

#### A1.2 Tier 1 key source assessment

As described in the IPCC Good Practice Guidance (IPCC, 2000), the Tier 1 method for identifying key sources categories assesses the impacts of various source categories on the level and the trend of the national emission inventory. Both level and trend assessment should be applied to an emission GHG inventory.

As concerns the level assessment, the contribution of each source category to the total national inventory level is calculated as follows:

#### Source Category Level Assessment = Source Category Estimate/Total Estimate

Therefore, key source categories are those which, when summed in descending order of magnitude, add up to over 95% of the total emission.

As far as the trend assessment is concerned, the contribution of each source category's trend can be assessed by the following equation:

Source Category Trend Assessment = Source Category Level Assessment · |(Source Category Trend – Total Trend)|

where the source category trend is the change in the source category emissions over time, computed by subtracting the base year estimate for a generic source category from the current year estimate and dividing by the current year estimate; the total trend is the change in the total inventory emissions over time, computed by subtracting the base year estimate for the total inventory from the current year estimate and dividing by the current year estimate.

As differences in trend are more significant to the overall inventory level for larger source categories, the results of the trend difference is multiplied by the results of the level assessment to provide appropriate weighting.

Thus, key source categories will be those where the source category trend diverges significantly from the total trend, weighted by the emission level of the source category.

Both level and trend assessment have been carried out for the Italian GHG inventory.

The results of the Tier 1 method are reported in Table A1.1.

As regards the trend assessment, as already mentioned, the equation reported above does not enable quantification in case the emission estimates for the current year are equal to zero. In this case, since it is important to investigate into the trend and the transparency of the estimate, the results of the level assessment or other qualitative criteria can be taken into account. In the Italian inventory this occurs only for  $SF_6$  from the production of  $SF_6$ .

Table A1.1 Results of the key sources analysis (Tier1)

The application of the Tier 1 gives as a result 17 key sources accounting for the 95% of the total levels uncertainty; when applying the trend analysis the key sources increased to 18 with some differences with respect to the previous list.

#### A1.3 Uncertainty assessment (IPCC Tier 1)

The Tier 2 method for the identification of key sources implies the assessment of the uncertainty analysis to an emission inventory.

As already mentioned, the IPCC Tier 1 has been applied to the Italian GHG inventory to estimate uncertainties in national greenhouse gas inventories.

The results of the approach are reported in Table A1.2. For the LULUCF sector, emission uncertainties have also been calculated but not included in the national total uncertainty of the inventory. Details on the Tier 1 method used for LULUCF are described in the relevant chapter, chapter 7, the results by category are reported in Table A1.3.

<sup>a</sup> the combined uncertainty has been calculated as explained in Chapter 7, 7.2.3 Uncertainty and time series consistency; in order to provide estimate of uncertainties in trend in national emissions introduced by emission factor and activity data, values for the uncertainty related to activity data and emission factor have been assigned by expert judgment, taking into account the final combined uncertainty **Table A1.3 Results of the uncertainty analysis for the LULUCF sector (Tier1)** 

Emission sources of the Italian inventory are disaggregated into a detailed level, 60 sources, according to the IPCC list in the Good Practice Guidance, which has been slightly revised taking into account national circumstances and importance. Uncertainties are therefore estimated for these categories. To estimate the uncertainty for both activity data and emission factors, information provided in the IPCC Good Practice Guidance as well as expert judgement has been used; standard deviations have also been considered whenever measurements were available.

The general approach followed for quantifying a level of uncertainty to activity data and emission factors is to set values within a range low, medium and high according to the confidence the expert relies on the value used. For instance, a low value (e.g. 3-5%) has been attributed to activity data derived from the energy balance and statistical yearbooks, medium-high values within a range of 20-50% for all the data which are not directly or only partially derived from census or sample surveys or data which are simple estimations. For emission factors, the uncertainties set are usually higher than those for activity data; figures suggested by the IPCC good practice guidance (IPCC, 2000) are used when the emission factor is a default value, low values are attributed to measured data whereas the uncertainty values are high in all other cases. Details of the figures can be found in Table A1.2.

The Tier 1 approach suggests an uncertainty of 3.2% in the combined GWP total emissions in 2003. The analysis also estimates an uncertainty of 2.4% in the trend between 1990 and 2003.

For the LUCF sector, the uncertainty value resulting from the Tier 1 approach is 71% in the combined GWP total emissions for the year 2003, whereas the uncertainty in the trend is 30%. Details of the figures are shown in Table A1.3.

Further investigation is needed to better quantify the uncertainty values for some specific source, nevertheless it should be noted that a conservative approach has been followed.

#### A1.4 Tier 2 key source assessment

The Tier 2 method can be used to identify key source categories when an uncertainty analysis has been carried out on the inventory. It is helpful in prioritising activities to improve inventory quality and reduce overall uncertainty.

Under the Tier 2, the source category uncertainties are incorporated by weighting the Tier 1 level and trend assessment results with the source category's relative uncertainty. Therefore the following equations:

Level Assessment, with Uncertainty = Tier 1 Level Assessment · Relative Source Uncertainty

*Trend Assessment, with Uncertainty = Tier 1 Trend Assessment · Relative Source Uncertainty* 

The results of the key source Tier 2 analysis are provided in Table A1.3

The application of the Tier 2 gives as a result 21 key sources accounting for the 95% of the total levels uncertainty; when applying the trend analysis the key sources increased to 22 with differences with respect to the previous list.

# ANNEX 2: DETAILED TABLES OF ENERGY CONSUMPTION FOR POWER GENERATION

In the following tables the detailed breakdown of total fuels consumed for electricity generation in the years 1990, 1995, 2000-2003 is reported. For each year data from three different sources are reported:

- output of the model used to estimate consumption and emissions for each plant type;
- detailed report by GRTN;
- data available in BEN.

For each source three kind of data are presented: electricity produced, physical quantities of consumed fuels and amount of energy used.

As one can notice from the following tables, there are not negligible differences in total consumption figures between GRTN and BEN. Both data sets are supposed to be based on the same data. As already said in paragraph 3.4, differences may be partially explained by the process of adapting GRTN data to BEN methodology. BEN considers for each fuel always the same heat value, adjusting the physical quantities accordingly. This calculation process combined with the reduction of fuel types from 17 to 12 add rounding errors and this may be responsible for the small difference between the energy consumption value in most of the years (between 0.0% and 0.9%, refer to last row of each table, last value).

Differences between those two data sets and the model output are also present, they can be improved (i.e. reduced) and depend on the modeller choice: a compromise between GRTN and the BEN data according to cross check done with other sources (UP or point source data).

There are also discrepancies in the estimates of the total electricity produced, refer to last row of each table, first value. They are rather small, between 0.1% and 0.8% and can be due to rounding errors. Not surprisingly the differences between the fuel quantities, when expressed in physical values are much bigger, range from 4 to 7%, with the year 2003 going up to an astonishing 17%.

In conclusion the main question of the accuracy of the underlining energy data of three key sources is connected to the unexplained discrepancy between BEN and GRTN in the estimates of electricity produced and of the energy content of the used fuels. The difference is small but it should occur because both data sets are derived from the same source. On the basis of this consideration, we decided to base the inventory on GRTN data that are expected to be more reliable. In particular because the EF used are based on the energy content of the fuel we have made an effort to reproduce with the model the GRTN energy consumption figure and ignored discrepancies in the electricity production or in the physical quantities of fuel used.

# Table A2.6 - Energy consumption for electricity production, year 2003

### ANNEX 3: ESTIMATION OF CARBON CONTENT OF COALS USED IN INDUSTRY

The preliminary use of the CRF software in 2001 underlined an unbalance of emissions in the solid fuel rows above 20%. A detailed verification pointed out to an already known fact for Italy: the combined use of standard IPCC emission factors for coals, national emission factors for coal gases and CORINAIR methodology emission factors for steel works processes produces double counting of emissions.

The main reason for this is the specific national circumstance of extensive recovery of coal gases from blast furnaces, coke ovens and oxygen converters for electricity generation. The emissions from those gasses are separately accounted for and reported in the electricity generation section.

An other specific national circumstance is the concentration of steel works in two sites, with integrated steel plants, coke ovens and electricity self-production. Limited quantities of steel are produced also in two additional locations. This has allowed for careful check of the processes involved and the emissions estimates at site level and, with reference to other countries, may or may not have exacerbated the unbalances in carbon emissions due to the use of EF developed for other industrial sites.

To avoid the double counting a specific methodology has been developed: it balances energy and carbon content of coking coals used by steelworks, industry, for non energy purposes and coal gasses used for electricity generation.

A balance is made between the coal used for coke production and the quantities of derived fuels used in various sectors. The iron and steel sector gets the resulting quantities of energy and carbon after subtraction of what is used for electricity generation, non energy purposes and other industrial sectors.

The base statistical data are all reported by BEN, with one exception, the methodology starts with a verification of the energy balance reported by BEN, see also Annex 5, table A5.3/.4, that seldom presents problems, and then apply the standard EFs to the energy carriers, trying to balance the carbon inputs with emissions. The exception mentioned refers to the recovered gasses of BOFs (Basic Oxygen Furnace) that are used to produce electricity but are not accounted for by BEN from year 1990 up to year 1999. From year 2000 those gasses are (partially) include in the estimate of blast furnace gas. The data used to estimate the emissions from 1990 to 1999 are reported by GRTN. The consideration of the BOF gasses do not change the following discussion, its contribution to the total emissions is quite limited.

Table A3.1 summarize the quantities of coal and coal by-products used by the energy system, all the data mentioned can be found in "enclosures 1/a, 2/a and 3/a" of BEN, see also Annex 5.

In the first box from top of the table we can see the quantities of coke, coke gas and blast furnace gas uses by the different sectors. In the second box are reported the quantities of the same energy carriers that are self-used, used for the production of coke of wasted.

Then in the final part of the table, the two coloured groups of cells report the verification of the input-output of two processes: coke ovens and the blast furnaces. The input –output is generally balanced for all the considered years, the small differences can be explained by statistical discrepancies. The following data are just memo summary of the quantities of fuels imported or exported by the system.

If we now look at Table A3.2, in the first two boxes from top we found the same energy data of table A3.1 valuated for their carbon content, according to the standard EF reported in Table 3.6 of the NIR. Then in the coloured cells we fund the balance of carbon inputs and outputs of two processes coke oven and blast furnaces. In this case there is no balance at all, and while the coke production process keep the balance within reasonable percentages, the blast furnaces shows an unbalance of more than 60%, it seems that it produces carbon. For the other years we found similar unbalances.

The rationale of the industrial process does not justify a similar increase in carbon emissions. There is usually no carbon in the iron ore used or in other additives used in the process, on the contrary a

limited quantities of the input of carbon (max 2%) is stocked in the produced steel (not considered here) and small quantities are also contained in the solid slag produced by the process.

All those data are produced with the energy statistical data and standard EF, if we add to this the process EF considered by the CORINAIR methodology, based on the quantities of steel or iron produced, we should add other quantities of carbon emissions to the already unbalanced total just described.

If the physical quantities of the coal by products reported by BEN are correct, as shows the energy balance, then the EFs have to be verified. In the meantime APAT decided to report according to the following principle: total carbon emissions at a certain location cannot be higher than carbon inputs from the imported coals. A sort of "bubble" concept applied to carbon emissions at sectorial level. Of the three main processes involved, coke ovens, blast furnaces and electricity production, the first and the latter appear to be balanced and/or are well monitored, so, pending further investigation of

EF, the changes have to be made in the blast furnaces estimates.

coke	coke gas	Blast furnace gas	NOTES		
8,46	8,469		For blast furnace		
	3,098	7,533	For electricity prod.

37,83	5		Blast fornace coal input		
7,80	5	import + stock change			

 Table A3.1 Energy balance, 2003, 10^9kcal

So in the end the methodology actually foresees as a first step the calculation of the total carbon inputs (imported fuels plus standard IPCC EFs), see table A3.1 column "total according to BEN". A second step foresee the use for the electric sector of the value directly calculated from the coal gasses used and the calculation of a "balance" quantity for blast furnaces, reference to column "total used for CRF" in table A3.1 . The "balance is the resulting quantity of emissions after subtraction of carbon emissions estimated for coke ovens, electricity production, other coal uses and non energy uses.

The resulting carbon quantities are correct but, when reported in the CRF format, they seems to be produced using very low EFs for coal produced  $CO_2$ , near to the natural gas EF, for the steel making process and quite high carbon emissions for the coal use to produce electricity.

Further investigations are planned, with a verification of the carbon content of the imported coals and of the coal gasses produced at various stages of the process, coke gas, blast furnace gas and BOF gas.

Table A3.2 Carbon balance, 2003, Mt CO<sub>2</sub>

## ANNEX 4: CO<sub>2</sub> REFERENCE APPROACH

#### A4.1 Introduction

The IPCC Reference Approach is a 'top down' inventory based on data on production, imports, exports and stock changes of crude oils, feedstock, natural gas and solid fuels. Estimates are made of the carbon stored in manufactured products, the carbon consumed as international bunker fuels and the emissions from biomass combustion.

The methodology followed is that outlined in the IPCC Guidelines (IPCC, 1997); table 1.A(b) of the Common Reporting Format "Sectoral background data for energy" - CO<sub>2</sub> from Fuel Combustion Activities - Reference Approach is a self sustaining explanation of the methodology. However it was necessary to make a few adaptations to allow full use of Italian energy and emission factor data (ENEA, 2002 [a]), and these are described in the following. The BEN (MAP, 2005 [a]) reports the energy balances for all primary and secondary fuels, with data on imports, exports and production. Refer to Annex 5, Tables A5.1-A5.8, for an example of the year 2003 and to the web site of the Ministry of Production Activities for the whole time series https://dgerm.attivitaproduttive.gov.it/dgerm/

Starting from those data and using the emission factors reported in chapter 3, Table 3.7, it is possible to estimate the total carbon entering in the national energy system. With time it has been developed a direct connection between relevant cells of the CRF tables and the BEN tables and a procedure to insert some additional activity data needed.

The 'missing' data refer to import – export of lubricants, petrol additives, asphalt, other chemical products with energy content, energy use of exhausted lubricants and the evaluation of marine and aviation bunkers fuels used for national traffic.

Those 'missing' data are in fact reported in the BEN but all mixed up together with other substances as sulphur and petrochemicals. The aggregate data do not allow the use of the proper emission factor so inventory is based on more detailed statistics from foreign trade surveys.

The carbon stored in products is estimated according to the procedure illustrated in the paragraph 3.9 and directly subtracted to the emission balance by the CRF software. It may be the case to underline that no direct subtraction of the energy content of the feedstock is performed by CRF. In the cases, as Italy, where those products are not considered in the energy balances this bring to an unbalanced control sheet, as discussed in the next session.

With reference to table 1.A(b) of the CRF 2003, the main energy data source is the BEN. We make reference to the BEN tables reported in Annex 5. In particular the following data are available:

1) crude oil imports and production;

2) natural gas data import;

3) import-export data of petrol, aviation fuel, other kerosene, diesel, fuel oil, LPG and virgin naphtha;

4) import-export data of bitumen and motor oil derive from foreign trade statistics, estimated by an ENEA consultant for the period 1990-1998. BPT data (MAP, 2005 [b]) are used from 1999 onwards;

5) import-export data of petroleum coke and refinery feedstock are also found in BEN; it has to be underlined that the data reported as "feedstock production" have been ignored because it is explicitly excluded by the IPCC methodology referring to petrochemical feedstock coming back to the refineries, subtracted from the non energy use estimate; therefore it cannot be considered as additional carbon inserted in the energy system;

6) all coal data are available in BEN, coke import-export included;

7) total natural gas import-export balance reflects BEN estimate (energy section), but the detailed quantities coming from different countries (relevant for the carbon EF estimate, see paragraph 3.9) are from foreign trade statistics or SNAM, the former national gas monopoly, fiscal budgets; natural

gas data show not negligible variations from source to source, with particular reference to the underground stocked quantities;

8) from 1990 to 2003 biomass consumption data are those reported in the BEN; it is well known that other estimates show much bigger, up to 50% more, quantities of used biomass, for example ENEA (ENEA, 2005); but the same source quotes BEN biomass consumption estimates as official statistics up to the year 2003, pending further investigations; the inventory follows the same methodology.

The following additional information is needed to complete table 1.A(b) of CRF 2003 and it is found in other sources:

- 1) Orimulsion, this fuel is mixed up with imported fuel oil (on the base of the energy content), the quantities used for electricity generation are reported by ENEL (ENEL, 2005), the former electricity monopoly, presently the only user of this fuel, in their environmental report. As long as the emission factors are quite different, a note is needed in the BEN, at least as a warning.
- 2) Motor oils and bitumen.
  - a) Data on those materials are mixed up in the no energy use by BEN, detailed data are available in BPT (MAP, 2005 [b]). The quantities of those materials are quite relevant for the no energy use of oil.
  - b) In the BEN those materials are estimated in bulk with other products to have an energy content of about 5100 kcal/kg. Average OECD data 9000 kcal/kg for bitumen and 9800 kcal/kg for motor oils. In the CRF those products are estimated with the OECD energy contend and this may explain part of the unbalance between imported oil and used products.

For further information please refer to the paper by ENEA (ENEA, 2002 [b]) in Italian.

#### A4.2 Comparison of the sectoral approach with the reference approach

The detailed inventory contains a number of sources not accounted for in the IPCC Reference Approach and so gives a higher estimate of  $CO_2$  emissions. The unaccounted sources are:

- Land use change and forestry
- Offshore flaring and well testing
- Waste incineration
- Non-Fuel industrial processes

In principal the IPCC Reference total can be compared with the IPCC Table 1A total plus the fugitive emissions arising from fuel consumption reported in 1B1 Solid Fuel Transformation and Table 2 Industrial Processes (Iron and Steel and Ammonia Production). Results show the IPCC Reference totals are between 0-4 % lower than the comparable 'bottom up' totals.

Differences between emissions estimated by the reference and sectoral approach are reported in the following Table A4.1.

	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
Sectoral approach	399.1	399.4	397.9	395.7	389.5	417.0	411.5	415.2	425.1	432.5	438.6	442.6	442.5	456.8
Reference approach	396.3	393.3	398.5	391.3	385.0	406.2	404.4	407.0	416.1	415.9	422.5	430.1	436.9	452.8
$\Delta$ %	-0.7	-1.5	0.1	-1.1	-1.2	-2.6	-1.7	-2.0	-2.1	-3.8	-3.7	-2.8	-1.3	-0.9

Table A4.1 Reference and Sectoral approach CO<sub>2</sub> emission estimates 1990-2003 (Mt) and percentage differences

There are a number of reasons why the totals differ and these arise from differences in the methodologies and the statistics used.

Explanations for the discrepancies:

- 1. The IPCC Reference Approach is based on statistics of production, imports, exports and stock changes of fuels whilst the 'bottom-up' approach uses fuel consumption data. The two sets of statistics can be related using mass balances (MAP, 2005 [a]), but these show that some fuel is unaccounted for. This fuel is reported under 'statistical differences' which consist of measurement errors and losses. A significant proportion of the discrepancy between the IPCC Reference approach and the 'bottom up' approach arises from these statistical differences particularly with liquid fuels.
- 2. In the power sector in the detailed approach statistics from producers are used, instead for the reference approach the BEN data are used. The two data sets are not connected; in the BEN sections used only the row data of imports-exports are contained. But if one considers the process of "balancing" the import production data with the consumption ones and the differences between the two data sets, a sizable part of the discrepancy may be connected to this reason only. An investigation is planned as soon as resources became available.
- 3. The 'bottom up' approach only includes emissions from the no energy use of fuel where they can be specifically identified and estimated such as with fertilizer production and iron and steel production. The IPCC Reference approach implicitly treats the non-energy use of fuel as if it were combustion. A correction is then applied by deducting an estimate of carbon stored from non-energy fuel use. The carbon stored is estimated from an approximate procedure which does not identify specific processes. The result is that the IPCC Reference approach is based on a higher estimate of non-energy use emissions than the 'bottom-up' approach.

The IPCC Reference Approach uses data on primary fuels such as crude oil and natural gas liquids which are then corrected for imports, exports and stock changes of secondary fuels. Thus the estimates obtained will be highly dependent on the default carbon contents used for the primary fuels.

The 'bottom-up' approach is based wholly on the consumption of secondary fuels where the carbon contents are known with greater certainty. In particular the carbon contents of the primary liquid fuels are likely to vary more than those of secondary fuels. Carbon content of solid fuels and of natural gas is quite precisely accounted for, a specific methodology for estimate carbon content of liquid fuel imports is at the moment only planned.

### ANNEX 5: NATIONAL ENERGY BALANCE, YEAR 2003

The following table reproduces the part expressed in amount of energy consumed of the National Energy Balance (BEN) of the year 2003.

The complete balance, containing the physical quantities as well as the amount of energy and a consistent time series from the year 1994 onwards, is also available on the web site: <a href="https://dgerm.attivitaproduttive.gov.it/dgerm/">https://dgerm.attivitaproduttive.gov.it/dgerm/</a>

Sectors and fuel definition have been translated here in English, but, of course, the tables on Internet are in Italian language. Definitions are very similar to their English equivalents so this should not be an obstacle to independent verifications of energy data sources for previous years.

The national energy balance is comprised of two "sets" of tables: from page 6 to page 14 the energy vectors are represented in physical quantities (kt) while from page 16 to page 24 they are expressed in energy equivalents (10^9 kcal).

Recalling what already said in Annex 2 related to the BEN reporting methodology (that prefers to use always the same lower heat value for each primary fuel in various years, to better follow the variable energy content of each shipment), we make reference here to the second set of tables. This means, for example, that the primary fuel quantities of two shipments of imported coal are "adjusted" using their energy content as the main reference (see Table A5.1) and the value reported in page 6 of the national energy balance (non reproduced here) is an "adjusted" quantity of kt. This process is routinely applied for most primary sources, including imported and nationally produced natural gas.

For the final uses of energy (Tables A5.7-8 and Tables A5.9-10) the same methodology is applied but is runs the other way: the physical quantities of energy vectors are the only values actually measured on the market and the energy content is actually estimated using fixed average estimates of lower heat value. Experience on the measure of the actual energy content of fuels shows minor variations from one to another year, especially for liquid fuels.

In the case of natural gas the use of a fixed heat value to summarize all transactions was particularly complicated due to the fact that we use fuel from four main different sources: Russia, Netherlands, Algeria and national production. From 2003-2004 onwards Norway and Lybia have also been added to the supply list. The big customers where actually billed according to the measured heat value of the natural gas delivered. After the end of the state monopoly on this marked the system has recently been changed. From 2004 onwards, the price makes reference to the energy content of natural gas and the metered physical quantities of gas delivered to all final customers are billed according to an energy content variable from site to site and from year to year. The BEN still tries to summarize all production and consumption using only one conventional heat value.

So for the estimations of liquid fuels used in the civil and transportation sector the most reliable data is the physical quantity and this is used to calculate emissions, using updated data for the emission factors, estimated from samples of marketed fuels.

For this reason we attach also the copies of tables, page 12 and 13 of BEN (see Tables A5.9-10), mirror sheet of the tables, page 22 and 23 of BEN (see Tables A5.7-8), that are the base for our emission calculation in the civil and transport sectors.

#### **ANNEX 6: NATIONAL EMISSION FACTORS**

Monitoring of the carbon content of the fuels used nationally is an ongoing activity at APAT. The principle is to analyse regularly the chemical composition of the used fuel or relevant activity statistics, to estimate the carbon content and the emission factor. For each primary fuel (natural gas, oil, coal) a specific procedure has been established.

#### Natural gas

IPCC methodology reports an emission factor for this energy carrier. Initially to estimate the methane content of the fuel, so that the correct emission factor for fugitive emissions could be evaluated a proper investigation has been performed among main users. Routine checks are performed by final uses to estimate chemical composition of natural gas and its energy value.

It has been found that the national marked is characterized by the commercialisation of natural gas of highly variable composition. Since 1990 natural gas has been produced nationally or imported by pipelines from Russia, Algeria and Netherlands. Moreover an NGL facility is importing gas from Algeria and Libya. In the recent years other countries have been added to the list.

Each of those natural gasses has peculiar properties and it is regularly analysed at the import gates, for budgetary reasons. Energy content for cubic meters and percentage of methane can vary considerably: national produced gas sold to the grid is almost 99% methane (% moles), the one coming from Algeria has less than 85% of methane and significant quantities of propane-butane. Carbon content varies significantly also.

Natural gas properties are quite stable with reference to the country of origin and chemical composition and speciation of gas from each country is regularly published by SNAM, the main national operators. Other information is also available from the final distribution companies.

So, for each year, the average methane and carbon content of the natural gas used in Italy are estimated using the international trade statistical data and a national emission factor is estimated. The list of factors for the years of interest is reported in Table A6.1.

	t	$CO_2$ / std cub	ic
	t CO <sub>2</sub> / TJ	mt	t CO <sub>2</sub> / tep
Natural gas (dry) IPCC	55.780	1.925	2.334

Natural gas (dry) '2003	55.287	1.950	2.313

 Table A6.1 Natural gas carbon emission factors

#### Diesel oil, petrol and LPG, national production

APAT has made an investigation of the carbon content of the main transportation fuels sold in Italy: petrol, diesel and LPG.

The job has been aimed to test the average fuels sold in the year 2000 and to collect the available information on previous years fuels. The aim of this work is the verification of CO<sub>2</sub> emission factors of the Italian energy system and specifically of the transportation sector. The results of analysis of fuel samples performed by "Stazione Sperimentale Combustibili" (APAT, 2003) are checked against the emission factors used in the Reference Approach of the Intergovernmental Panel for Climate Change (IPCC, 1997) and the emission factors considered in the COPERT III programme of the European Environment Agency (EEA, 2000).

Those two methodologies are widely used to prepare data at the international level but, when applied to the Italian data set produces results with significant differences, around 2-4%. The reason

has been traced back to the emission factors, that is referred to the energy content of the fuel for IPCC and to the physical quantities for the COPERT methodology.

The results of the study performed by APAT link the chemical composition of the fuel to the LHV for a series of fuels representative of the national production in the years 2000-2001, allowing for more precise evaluations of the emission factors.

IPCC-OECD emission factors for diesel fuels and LPG are almost identical to the experimental results (less than 1% difference), and it has been decided to use IPCC emission factors for the period 1990-1999 and the measured EF from the year 2000 onwards.

Relevant quantities (about 50%) of LPG used in Italy are imported. The measured values refer only to the products produced in Italy, IPCC emission factors is used as a default.

For petrol instead the IPCC-OECD emission factors is quite low and it has to be upgraded, the reason may be linked to the extensive use of additives in recent years to reach a high octane number after the lead has been phased out. For 2000 and the following years the experimental factor will be used, for the period 1990-1999 it has been decided to use an interpolate factor between IPCC emission factors and the measured value, using the LHV as the link between the national products and the international database. No other information was available.

The list of emission factors for the different years is reported in Table A6.2.

	t CO <sub>2</sub> / TJ	t CO <sub>2</sub> / t	t CO <sub>2</sub> / tep
Petrol, 1990-'99, IPCC /OECD	68.531	3.015	2.872

LPG, test data, 2000	64.936	2.994	2.717

 Table A6.2 Fuels, national production, carbon emission factors

#### Fuel oil, imported and produced

With reference to fuel oil the main information available was a sizable difference in carbon content between high sulphur and light sulphur brands. IPCC emission factors generally refer to the light sulphur product.

The data where elaborated from literature and from an extensive series of samples (more than 400) analysed by ENEL and made available to APAT.

Carbon content varies to a certain extent also between the medium sulphur content and the very low sulphur products, but the main discrepancies refer to the high sulphur type.

According to the available statistical data, it was possible to trace back to the year 1990 the produced and imported quantities of fuel oil, divided between high and low sulphur products and to estimate the average carbon emission factor for the years of interest, see Table A6.3 for details.

	t CO <sub>2</sub> / TJ	t CO <sub>2</sub> / tep
Fuel oil, 1990 average	76.539	3.202
Fuel oil, 1990 average	76.565	3.203
Fuel oil, 1995 average	76.650	3.207
Fuel oil, 2000 average	76.699	3.209
Fuel oil, 2003 average	76.695	3.209

 Table A6.3 Fuel oil, average of national and imported products, carbon emission factors

### Coal imports

With reference to coal the information available nationally we found a sizable difference in carbon content of various imported coals. This finding was expected and it can be linked to the hydrogen content and to the LHV of the coal.

We found also that supply of coal is not stable over time: the quantities shipped by the main exporters change considerably from year to year, moreover new suppliers have been added to the list in the last few years. This fact derives from the specific national circumstances of Italy that has a negligible national production and buys the product on the word market.

So an attempt was made to find out a methodology that allow for a more precise estimation of the carbon content of this fuel. It is possible, using literature data for the coals and detailed statistical records of international trade, to find out the weighted average of carbon content and of the LHV of the fuel imported to Italy each year. The actually still unresolved problem is how to properly link statistical data, referred to the coal "as is" without specifying the moisture and ash content of the product, to the literature data that refer to sample coals.

We envisage to improve the quality of the collected statistical data including moisture content of coals but presently we overcome this obstacle with the following procedure:

- using an ample set of experimental data on coals imported in a couple of years on an extensive series of samples, more than 200, analysed by ENEL (the main electricity producing company in Italy) it was possible to correlate "as is" LHV and carbon content to the average properties of the coals imported in the same period of time and calculated from literature data (EMEP/CORINAIR, 2001);
- for each inventory year it is possible to calculate the weighted average of LHV and carbon content of imported coals using available literature data;
- using this calculated data and the correlation found out it is possible to estimate the carbon content of the average "as is" coal reported in the statistics.

Using this methodology and the available statistical data, it was possible to trace back to the year 1990 the average LHV of the imported coal and estimate the average carbon EF for each year, see table A6.4 for same details. The results do not show impressive changes from year to year, any way a noticeable difference of about 1.5% in the emission factor is highlighted in the table.

This methodology can be questioned and certainly can be improved; we continue to use it because, in our view, its use improves the quality of our reporting.

Table A6.4 – Coal, average carbon emission factors

## **ANNEX 7: CRF TREND TABLES FOR GREENHOUSE GASES**

This appendix shows a copy of Tables 10s1-10s5 from the Common Reporting Format 2003, submitted in 2005, in which time series of emission estimates for the following gases are reported:

- CO<sub>2</sub>
- CH<sub>4</sub>
- N<sub>2</sub>O
- HFCs, PFCs, SF<sub>6</sub>
- All gases and sources categories

#### Table A7.1 CO<sub>2</sub> emissions trends, CRF year 2003

### **ANNEX 8: METHODOLOGIES, DATA SOURCES AND EMISSION FACTORS**

This appendix shows a copy of Tables I-1 - I-4 on methodologies, data sources and emission factors used for the Italian inventory communicated to the European Commission under the implementing provisions for the compilation of The European Community Inventory.

#### Table A8.1 Methods, activity data and emission factors used for the Italian Inventory

#### <u>ANNEX I</u>

#### Table for methodologies, data sources and emission factors used by Member States for EC key sources for the purpose of Article 4(1)(b)

Information on methods used could be the tier method, the model or a country-specific approach. Activity data could be from national statistics or plant-specific. Emission factors could be the IPCC default emission factors as outlined in the revised 1996 IPCC guidelines for national greenhouse gas inventories and in the IPCC good practice guidance, country-specific emission factors, plant-specific emission factors or CORINAIR emission factors developed under the 1979 Convention on Long-Range Transboundary Air Pollution.

#### Table I -1: Community summary report for methods, activity data and emission factors used (Energy)

#### Legend for tables I -1 to I -4

(1) Key sources of the Community. To be completed by Commission/EEA with results from key category analysis from previous inventory submission

(2) Use the following notation keys to specify the method applied: C (CORINAIR), T1a, T1b, T1c (IPCC Tier 1a, Tier 1b and Tier 1c, respectively), COPERT X (Copert Model X = Version) D (IPCC default), RA (Reference Approach), CS (Country Specific). T2 (IPCC Tier 2), T1 (IPCC Tier 1), T3 (IPCC Tier 3), M (Model) If using more than one method within one source category, enumerate the relevant methods. Explanations regarding country-specific methods or any modifications to the default IPCC methods, as well as information regarding the use of Different methods per source category where more than one method is indicated, should be provided in the documentation box. (3) Use the following notation keys to specify the sources of activity data used NS (national statistics), IS (International statistics), AS (associations, business organizations) RS (regional statistics), PS (Plant Specific data). Q (specific questionnaires, surveys) If keys above are not appropriate for national circumstances, use additional keys and explain those in the documentation box. Where a mix of AD sources has been used, use different notations in one and the same cells with further explanations in the documentation box. (4) Use the following notation keys to specify the emission factor used: D (IPCC default), CS (Country Specific), C (CORINAIR), PS (Plant Specific). Where a mix of emission factors has been used, use different notations in one and the same cells with further explanations in the documentation box.

#### **Documentation box:**

\* The full information on methodological issues, such as methods, activity data and emission factors used, can be found in the relevant sector sections of chapter 5 of the NIR. If any additional information is needed
To understand the content of this table, use this documentation box to provide references to the relevant section of the NIR where further details can be found.
\* Where a mix of methods/emission factors has been used within one source category, use this documentation box to specify those methods/emission factors for the various sub-sources where they have been applied

where a mix of methods emission factors has been used whilm one source category, use this documentation box to specify those methods emission factors for the various sub-source category.

(see also footnotes 2 to 4 to this table).
